Abstract

This document specifies the semantics and behavior of the Hare programming language and serves to inform the development of compilers and programs for its use.

The scope of this document only covers the language itself (its grammar and semantics). The document does not specify any parts of the runtime library, nor does it specify additional details of the environment or the programming libraries available in that environment.

This specification is a DRAFT, and is not considered authoritative. Revisions to this draft are developed under the direction of the Hare project on SourceHut at [https://sr.ht/~sircmpwn/hare](https://sr.ht/~sircmpwn/hare), and the final specification will be published there as well. You may also contact the editor via email to Drew DeVault <sir@cmpwn.com>.

1 Introduction

1.1 The purpose of this document is to promote the portability of Hare programming systems and to serve as a reference for implementors and users of Hare programming environments.

1.2 Numbered text in this document is authoritative unless otherwise noted.

1.3 Sentences displayed in italics are non-authoritative (they are informative).

>This is an example of informative text.

1.4 The abstract and appendices are informative.

1.1 Copyright

>This document is licensed under the terms of CC-BY-ND. Free redistribution of this document is permitted, but derivative works are not allowed. Software which implements this specification are not considered derivative works; you may freely apply this specification as such without restriction.
2 Scope

2.1 This document establishes the form and semantics of the Hare programming language. It specifies:

2.1.1 The representation of Hare programs.
2.1.2 The syntax and constraints of the Hare language.
2.1.3 The semantic rules for the correct interpretation of a Hare program.

2.2 This standard does not specify:

2.2.1 The means by which program source code is processed by an interpreter or compiler.

However, «Appendix ??: Hare compiler conventions» provides an informative reference of common conventions for compiler and interpreter programs.

2.2.2 The means by which the environment interprets Hare programs.

2.2.3 The minimum requirements or maximum capabilities of a system capable of interpreting Hare programs.
3 Terms and definitions

3.1 abort: a process in which the «5.4: Execution environment» immediately proceeds to the program teardown step «5.4.3: Execution environment».

3.2 alignment: a specific multiple of an octet-aligned storage address at which some data is required to be stored. The size of an object must be a multiple of its alignment.

Example An object with an alignment of 8 may be stored at addresses 8, 16, 32, and so on; but not at address 4.

3.3 character: a single Unicode code-point encoded in the UTF-8 format.

3.4 expression: a description of a computation which may be executed to obtain a result with a specific result type.

3.5 expression class: a grouping of expressions with similar properties or for grammatical disambiguation.

3.6 implementation-defined: a detail which is not specified by this document, but which the implementation is required to define.

3.7 operand: an input into an operator, together they form an operation. An operand is an expression, and the input to the operator shall be its result.

3.8 padding: unused octets added to the storage of some data in order to meet a required alignment. The value of these octets is undefined.

3.9 size: the number of octets required to represent some data, including padding.

3.10 undefined: a detail for which no definition is provided, neither by this specification nor by the implementation. Programs which rely on these details are non-conforming.
4 Conformance

4.1 "Shall" is interpreted as a requirement imposed on the implementation or program; and "shall not" is interpreted as a prohibition.

4.2 "May" is used to clarify that a particular interpretation of a requirement of this specification is considered within the acceptable bounds for conformance. Conversely, "may not" is used to denote an interpretation which is not considered conformant.

4.3 A strictly conforming implementation shall meet the following requirements:

   4.3.1 It shall implement all of the behavior defined in the authoritative text of this specification.

   4.3.2 It shall not implement any behavior which is included by «2.1: Scope» but is not defined by this specification.

   This is to say that vendor extensions are prohibited of conformant implementations.

   4.3.3 It may implement behavior which is excluded by «2.2: Scope» and which is not defined by this specification.

4.4 A conforming freestanding implementation shall implement all requirements of this specification except for those defined in «??: Runtime Library». A conforming hosted implementation shall implement all requirements of this specification, including those defined in «??: Runtime Library».

Some language features require the implementation to provide the features defined by «??: Runtime Library». In order to use a conformant freestanding implementation, the program may be required to provide its own implementation of the features defined by «??: Runtime Library»; or refrain from using language features which require these implementations.
5 Program environment

5.1 The implementation translates source files and executes programs in two phases, respectively referred to as the translation phase and the execution phase. The context in which these phases occur is referred to as the translation environment and the execution environment.

5.2 Translation environment

5.2.1 A Hare program consists of one or more source files which are provided to the translation phase. A source file shall be represented as UTF-8 text.

5.2.2 Each source file is a member of exactly one module, and the collective source files for a module form a translation unit. Each module may define its own private types, data, procedures, and so on, for the purpose of accomplishing its tasks. It may also export these types for other modules to use.

5.2.3 A Hare program may be translated incrementally, rather than all at one time. However, the composite source files of a single translation unit must be compiled together. Once compiled, an opaque representation of their exported interface (the identifiers and types of their exported procedures, data, and types) provides sufficient information to translate other units which require the module. The translated modules may be composed into the final program at the last step.

5.2.4 If the source files for a translation unit are not changed, the translated module may be used repeatedly without repeating the translation step.

5.3 Translation steps

5.3.1 The list of source files constituting the translation unit are identified. Steps «5.3.2: Translation steps» and «5.3.3: Translation steps» are repeated for each source file.

5.3.2 Lexical analysis is conducted on the source file, translating it into a stream of tokens.

5.3.3 Syntax analysis is conducted on the token stream, mapping the tokens to an abstract syntax tree (AST). The Hare grammar defines the relationships between tokens necessary to produce a valid AST.

5.3.4 Logical analysis is conducted on the ASTs. In this step, the implementation verifies the constraints imposed on the program. The result of this step is a verified program module. In this step, colloquially referred to as the "check" step, a module composed of several source files is consolidated into a single verified program module.

5.3.5 Once the verified program module is obtained in the translation phase, the remainder of
the translation phase shall be completed with no further diagnostic messages, except in the case where external factors from the execution environment prevent successful completion.

Example Memory exhaustion or lack of disk space are situations which may cause a failure in the remainder of the translation process.

5.3.6 The verified program module is combined with any applicable external modules and translated into a single program image which is suitable for interpretation by the execution environment.

5.4 Execution environment

5.4.1 Two execution environments are defined: hosted and freestanding. The implementation must support a freestanding environment; support for a hosted environment is optional.

5.4.2 During program startup, the execution environment shall initialize all global declarations to their initial values, call all initialization functions in an unspecified order, then transfer control to the program entry point. The manner of this initialization is implementation-defined.

5.4.3 During program teardown, the execution environment shall call all finalization functions in an unspecified order, then terminate.

Forward references: «??: Initialization functions», «??: Finalization functions»

5.4.4 The freestanding environment

5.4.4.1 The name and signature of the program entry point function is undefined in the freestanding environment.

5.4.5 The hosted environment

5.4.5.1 In the hosted environment, the program entry point shall be an exported function named main in the root namespace. It shall have no parameters and a result type of void.

The signature of a conformant entry point follows:

\[
\text{export fn main() \ void;}
\]

The program shall provide this function in the root namespace.

5.4.6 Program execution

5.4.6.1 The evaluation of an expression may have side-effects in addition to computing a value. Calling a function or modifying an object is considered a side-effect.

5.4.6.2 If the implementation is able to determine that the evaluation of part of an expression is not necessary to compute the correct value and cause the same side-effects to
occur in the same order, it may rewrite or re-order the expressions or sub-expressions to produce the same results more optimally.

*The interpretation of this constraint should be conservative. Implementations should prefer to be predictable over being fast. Programs which require greater performance should prefer to hand-optimize their source code for this purpose.*

Forward references: «6.6: Expressions»

## 5.5 Diagnostics

5.5.1 If the constraints are found to be invalid during the translation phase, the implementation shall display an error indicating which constraint was invalidated, and indicate that the translation has failed in whatever manner is semantically appropriate.

*On a Unix system, the semantically appropriate indication of failure is to exit with a non-zero status code.*

5.5.2 In the translation environment, if the implementation is able to determine that multiple constraints are invalid, it may display several diagnostic messages.

5.5.3 If the constraints are found to be invalid during the execution phase, a hosted implementation shall abort the execution phase, display a diagnostic message, and indicate that the execution has failed in whatever manner is semantically appropriate.
6 Language

6.1 Notation

A summary of the language syntax is given in «Appendix ??: Language syntax summary».

6.1.1 The notation used in this specification indicates non-terminals with italic type, terminals with bold type, and optional symbols use "opt" in subscript. Non-terminals referenced in the text use the expression notation. The following example denotes an optional expression enclosed in literal braces:

\{ expression\_{opt} \}

6.1.2 When there are multiple options for a single non-terminal, they will either be printed on successive lines, or the preceding authoritative text will use the key phrase "one of".

6.1.3 Most grammatical constructs are tolerant of white-space characters inserted between their terminals. However, some are not—these will use the key phrase "exactly" in their grammar description.

6.1.4 A non-terminal is defined with its name, a colon (":"), and the options; indented and shown with one option per line. For example, switch-cases is defined like so:

```
switch-cases:
    switch-case ;
    switch-case ; switch-cases
```

6.1.5 Additionally, text may appear in the notation without italics or bold font; it appears in the same style as the authoritative text. Such examples are used to describe how a particular terminal sequence is matched when enumerating all of the possibilities is not practical.

```
rawstring-char:
    Any character other than \`
```

6.2 Lexical analysis

```
token:
    constant
    identifier
    keyword
    name
```

6.2.1 A token is the smallest unit of meaning in the Hare grammar. The lexical analysis phase processes a UTF-8 source file to produce a stream of tokens by matching the terminals with the input text.
6.2.2 Tokens may be separated by white-space characters, which are defined as the Unicode code-points U+0009 (horizontal tabulation), U+000A (line feed), and U+0020 (space). Any number of whitespace characters may be inserted between tokens, either to disambiguate from subsequent tokens, or for aesthetic purposes. This whitespace is discarded during the lexical analysis phase.

Within a single token, white-space is meaningful. For example, the string-literal token is defined by two quotation marks " enclosing any number of literal characters. The enclosed characters are considered part of the string-literal token and any whitespace therein is not discarded.

6.2.3 The lexical analysis process consumes Unicode characters from the source file input until it is exhausted, performing the following steps in order. At each step, it shall consume and discard white-space characters until a non-white-space character is found, then consume the longest sequence of characters which constitutes a token and emit it to the token stream.

6.2.4 The terminal sequence // is used to mark a comment. When the lexical analyzer encounters this terminal sequence, it shall discard it and all subsequent characters until a line feed U+000A is encountered, then resume normal processing.

6.3 Keywords

keyword: one of:

abort align alloc append as assert bool break case const continue def defer delete else enum export f32 f64 false fn for free i16 i32 i64 i8 if insert int is len let match null nullable offset return rune size static str struct switch true type u16 u32 u64 u8 uint uintptr union use vaarg vaend valist vastart void yield —

6.3.1 Keywords (or reserved words) are terminals with special meaning. These names are case-sensitive. Keywords are reserved for elements of the syntax and shall not appear as user-defined names, such as «6.4 Identifiers» and labels.
6.4 Identifiers

identifier: exactly:
  name
name name :: identifier

name: exactly:
  nondigit
nondigit name alnum
	nondigit: one of:
    a b c d e f g h i j k l m
    n o p q r s t u v w x y z
    A B C D E F G H I J K L M
    N O P Q R S T U V W X Y Z
    _

digit: one of:
  0 1 2 3 4 5 6 7 8 9

alnum:
  digit
  nondigit

6.4.1 An identifier is a user-defined name which denotes a module, object, function, type alias, struct or union member, or enumeration member.

6.4.2 An identifier is only meaningful within a specific scope of the program. The scope is defined by the region of the AST in which the identifier is applicable; it may be the program, a translation unit, a sub-unit, a function, or an expression-list. The identifier is considered visible within the region that defines its scope.

6.4.3 A translation unit is assigned a unique namespace within the program. These namespaces may be nested recursively; that is to say that a translation unit may have a parent which is another translation unit. One translation unit may be assigned to the root namespace, which has no name.

6.4.4 Identifiers declared within a translation unit scope are assigned the namespace of the translation unit. The double-colon terminal :: is used to denote the namespace of an identifier, ordered from least to most specific.

6.4.5 An identifier is either fully-qualified or unqualified. Unqualified identifiers require the context of their enclosing scope to be interpreted unambiguously. Fully-qualified identifiers are used for exported identifiers, and include the namespace in which they reside.

Example The fully-qualified identifier sys::start::start_ha qualifies the un-qualified identifier start_ha with the start namespace, which is itself a member of the sys namespace.

6.4.6 An identifier without the namespace qualification may be fully-qualified regardless, if it exists in the root namespace.
6.4.7 The implementation may define the maximum length of an identifier or name.

6.5 Types

\texttt{type:}
\begin{verbatim}
  \texttt{const}_{opt} \ !_{opt} \ storage-class
\end{verbatim}

\texttt{storage-class:}
\begin{itemize}
  \item scalar-type
  \item struct-union-type
  \item tuple-type
  \item tagged-union-type
  \item slice-array-type
  \item function-type
  \item alias-type
  \item unwrapped-alias
  \item string-type
\end{itemize}

\texttt{scalar-type:}
\begin{itemize}
  \item integer-type
  \item floating-type
  \item pointer-type
  \item rune
  \item bool
  \item valist
  \item void
\end{itemize}

6.5.1 A type defines the storage and semantics of a value. The attributes common to all types are its size, in octets; its alignment, in octets; its constant or mutable nature; its error flag, or lack thereof; and its default value. The size, alignment, and default value of a type may be undefined.

6.5.2 The implementation shall assign a globally unique ID to every type, in a deterministic manner, such that several subsequent translation environments, perhaps with different inputs, will obtain the same unique ID; and such that distinct types shall have distinct IDs. This specification details under what circumstances two types are equivalent to one another, and thus shall have the same ID. For all types, any two types are distinct if their type class, their constant or mutable nature, their error flag or lack thereof, or their default values, are distinct. Each type class may impose additional distinguishing characteristics on their types, which are specified in their respective sections.

6.5.3 Some types have an undefined size. This includes function-type, and some cases of slice-array-type.

6.5.4 Some types have an undefined default value. If the default value of such a type would be used, the implementation shall instead print a diagnostic message and abort the translation phase.
6.5.5 The `const` terminal, when used in a type specifier, enables the constant flag and prohibits write operations on any value of that type. Types without this attribute are considered mutable by default.

6.5.6 The `!` terminal, when used in a type specifier, sets the error flag for this type.

6.5.7 A scalar type, also called a *built-in* or *primitive* type, stores one value at a specific, pre-defined precision. Scalar types are the most basic unit in the Hare type system. Other types are referred to as *aggregate types*, with the exception of alias types, which may be either scalar or aggregate.

6.5.8 The *type class* of a type is defined for scalar types as the terminal which represents it, for example `i32`.

### 6.5.9 Integer types

```
integer-type:  one of:
i8  i16  i32  i64  u8  u16  u32  u64  int  uint  size  uintptr
```

6.5.9.1 Integer types represent an integer value at a specific precision. These values are either *signed* or *unsigned*; which respectively are and are not able to represent negative integers. Zero is not negative. Integer types are considered *numeric types*.

6.5.9.2 Signed integer types shall be represented in two’s complement form.

6.5.9.3 The endianness (byte order) of integer types shall be implementation-defined.

6.5.9.4 The precision of `i8`, `i16`, `i32`, `i64`, `u8`, `u16`, `u32`, and `u64` are specified by the numeric suffix, which represents their precision in bits. Of those, types prefixed with `u` are unsigned, and those prefixed with `i` are signed.

6.5.9.5 The precision of `int` and `uint` are implementation-defined. `int` shall be signed, and `uint` shall be unsigned. Both types shall be at least 32-bits in precision. The precision in bits shall be a power of two.

6.5.9.6 The precision of `size` is implementation-defined. It shall be unsigned and shall be able to represent the maximum length of an array type. The precision in bits shall be a power of two.

6.5.9.7 The precision of `uintptr` is implementation-defined. It shall be able to represent the value of any pointer-type (including `null`) as an integer. It shall be unsigned.

6.5.9.8 The alignment of integer types shall be equal to their size in octets.

6.5.9.9 The default value of an integer type shall be zero.

*The following table is informative.*
### 6.5.10 Floating point types

**floating-type:**

- `f32`
- `f64`

6.5.10.1 Floating point types shall represent approximations to real numbers. Floating point types are considered numeric types.

6.5.10.2 The bit layout of floating point types shall be implementation-defined.

6.5.10.3 The alignment of floating point types shall be equal to their size in octets.

6.5.10.4 The default value of a floating point type shall be zero.

### 6.5.11 Rune types

6.5.11.1 The `rune` type represents a Unicode codepoint, encoded as a `u32`.

### 6.5.12 Flexible constant types

6.5.12.1 Flexible constant types represent floating, integer, or rune constants whose result type has not been determined. The size and alignment of flexible constant types shall be undefined. `iconst` and `fconst` are considered numeric types.

6.5.12.2 An `iconst` shall have maximum and minimum values associated with it, which shall be represented as signed integers with sufficient precision to store an `i64`. The minimum value shall represent the smallest integer constant which has this result type, and the maximum value shall represent the largest. The minimum shall always be less than or equal to the maximum, and the type shall be considered unsigned if and only if the minimum is greater than or equal to 0.

* implementation-defined
+ undefined
6.5.12.3 The default type for \texttt{fconst} shall be \texttt{f64}. The default type for \texttt{iconst} shall be \texttt{int} if the maximum and minimum are within \texttt{int}'s range, and \texttt{i64} otherwise. The default type for \texttt{rconst} shall be \texttt{rune}.

6.5.12.4 A flexible constant type may be lowered to a different type by the «6.10: Flexible constant promotion algorithm», causing all instances of that type within the translation environment to be replaced by the new type. If a flexible constant type hasn’t been lowered by the end of the translation phase, it shall be lowered to its default type.

6.5.12.5 There is no grammar for defining flexible constant types. They are for internal use only, as the result type of \texttt{integer-constant}, \texttt{floating-constant}, and \texttt{rune-constant}.

6.5.12.6 Each constant with a flexible result shall have a distinct type.

6.5.12.7 If a flexible constant type is embedded within another type, it shall first be lowered to its default type.

\textit{This is intended to ease implementation, in order to prevent a type's ID, size, and alignment from changing partway through the translation phase.}

6.5.13 \textbf{Pointer types}

\begin{verbatim}
pointer-type:
  * type
  nullable * type
\end{verbatim}

6.5.13.1 A pointer type is an indirect reference to an object of a secondary type. The notation of a pointer type is a \texttt{*} prefix before the secondary type.

6.5.13.2 A normal pointer type shall always refer to a valid secondary object. A pointer type prefixed with \texttt{nullable} is considered a \textit{nullable pointer type}, and shall refer to either a valid secondary object or to a special value called \texttt{null}.

6.5.13.3 The representation of a pointer type shall be implementation-defined, and it shall have an implementation-defined length and alignment.

6.5.13.4 The default value of a nullable pointer type is null. The default value of a non-nullable pointer type is undefined.

6.5.13.5 A pointer type shall be equivalent to another pointer type only if they share the same secondary type and nullable status.

6.5.14 \textbf{Other primitive types}

\textbf{The \texttt{bool} type}

6.5.14.1 The \texttt{bool} type represents a boolean value, which may have one of two states: true or false.

6.5.14.2 The boolean type representation shall be equivalent to the \texttt{u8} type. Any non-zero value shall be interpreted as true, and zero shall be interpreted as false.

6.5.14.3 The default value of a boolean type is false.
The null type

6.5.14.4 The null type shall have the same representation as a pointer and can only store a specific, implementation-defined value (the null value).

6.5.14.5 There is no grammar for defining a value of type null, or a sub-type of null. It is for internal use only, as the type of the null constant.

The valist type

6.5.14.6 The valist type is provided for compatibility with the C programming language as specified by ISO/IEC 9899:2011. Implementation support is optional: implementations which do not provide C ABI compatibility must parse this type, print a diagnostic message, and abort.

6.5.14.7 The size and alignment of the valist shall be an implementation-defined value which shall be at least eight, and shall be divisible by eight.

6.5.14.8 Copying a valist value via an Assignment expression shall be equivalent to the "va_copy" macro described by ISO/IEC 9899:2011 section 7.16.1.2.

The void type

6.5.14.9 The void type represents a non-existent value, and shall have no storage.

6.5.15 Struct and union types

struct-union-type:

struct @packed_opt { struct-union-fields }
union { struct-union-fields }

struct-union-fields:

struct-union-field , opt
struct-union-fields

struct-union-field:

offset-specifier_opt name : type
offset-specifier_opt struct-union-type
offset-specifier_opt identifier

offset-specifier:

@offset ( expression )

6.5.15.1 The struct type and union type are aggregate types, which collect multiple types, name them, and assign them offsets within their storage area. A struct type stores each value at a different offset; a union type stores all of its values at the same offset. A type defined with the struct terminal is a struct type and uses the struct type class; if the union terminal is used the type is a union type with the union type class.

6.5.15.2 The struct-union-fields list denotes, in order, the subvalues which are collected by a struct or union, and potentially assigns a name to each.

6.5.15.3 For a struct type, the offset of each field is equal to the minimum aligned offset
which would meet the alignment requirements of the field’s type and which is
greater than the offset of the previous field plus the size of the previous field.
The implementation shall add padding to meet the alignment requirements of
struct fields. For a union type, the offset of all members is zero. Padding shall
additionally be added to the end of a struct type such that the total size of the struct
type modulo its alignment is zero.

6.5.15.4 For a struct type using the @packed modifier, the offset of each field shall be
computed without respect to alignment, such that each field’s offset is equal to the
offset of the previous field plus the size of the previous field. No additional padding
shall be added to the end of the struct type in this case. If the alignment of the
struct fields or the struct type itself would not meet the alignment requirements for
their respective type, the behavior is implementation defined. The implementation
shall either raise a diagnostic message and terminate the translation phase, or shall
support unaligned memory accesses (perhaps at a cost to performance).

6.5.15.5 The type of each struct or union field shall have a definite, non-zero size.

6.5.15.6 If given, the offset-specifier shall override the computed offset for a given field. If
the user-defined offset for a field would not meet the alignment requirements for
that type, the behavior is implementation-defined. The implementation shall either
raise a diagnostic message and terminate the translation phase, or shall support
unaligned memory accesses (perhaps at a cost to performance).

6.5.15.7 The expression given for the offset-specifier shall be limited to the «6.8: Translation
compatible expression subset», and shall have an integer type and a positive or zero
value.

6.5.15.8 The offset-specifier shall not be given for a union type.

6.5.15.9 A union type’s size is the maximum size among its fields. A struct type’s size is
the sum of $S$ for $S = O + Z$ among its fields, where $O$ is that field’s offset and $Z$
is that field’s size.

6.5.15.10 The default value of a struct or union type shall be defined as a value whose fields
assume the default values of their respective types. If two or more fields have
overlapping storage (as defined by the bounds of their offsets and size), and any of
their types does not have a default value, the default value of all of these fields shall
be undefined. If any field’s default value is undefined, the struct or union type’s
default value shall also be undefined.

6.5.15.11 If the struct-union-type form of struct-union-field is given, the parent type shall
collect the fields of the child type as its own. The offset of each field within the
child type shall be the sum of the offset within the child type and the offset the child
type occupies within the parent struct. The identifier form shall be interpreted in
the same manner as a struct-union-type if it refers to a type alias of a struct or union
type, otherwise a diagnostic message shall be printed and the translation phase
shall abort.

Forward references: «6.5.21 Type aliases»

6.5.15.12 A struct or union type shall be equivalent to another struct or union type if their
fields are of equivalent name, type, and offset, without respect to the order of their
appearance in the program source.
The following types are equivalent:
struct { a: int, b: int }
struct { a: int, struct { b: int } }

6.5.15.13 Each field name (including names of embedded fields) shall be unique within the set of all field names of the struct-union-type.

6.5.16 Tuple types

tuple-type:
( tuple-types )

tuple-types:
  type , type , opt
  type , tuple-types

6.5.16.1 A tuple type stores two or more values of arbitrary types in a specific order. It is similar to a struct type, but without names for each of its subvalues. Each value is stored at a given offset, possibly with padding added to meet alignment requirements.

6.5.16.2 The offset of each value is equal to the minimum aligned offset which would meet the alignment requirements of the value’s type and which is greater than the offset of the previous value plus the size of the previous value type. The implementation shall add padding to meet the alignment requirements of tuple values.

6.5.16.3 The size of a tuple is the sum of the sizes of its value types plus any necessary padding. The alignment is the maximum alignment among its value types.

6.5.16.4 The type of each tuple value shall have a definite, non-zero size.

6.5.16.5 The default value of a tuple type shall be defined such that its values assume the default values of their respective types. If any of the subtypes do not have a default value, neither does the tuple type.

6.5.16.6 Two tuple types shall be equivalent to each other if they have the same value types in the same order.

6.5.17 Tagged union types

tagged-union-type:
( tagged-types )
tagged-types:
  type | type | opt
  type | tagged-types

6.5.17.1 A tagged union stores a value of one of its constituent types, as well as a tag which indicates which of the constituent types is selected. The constituent types
are defined by tagged-types.

6.5.17.2 The representation of a tagged union shall be a u32, in which the tag value is stored, followed by sufficient space to store any of the possible constituent types. Padding shall be inserted prior to the tag if necessary to meet the maximum alignment among the tagged union members and the u32 field.

The representation of (u8 | i16) is equivalent to

```c
struct {
    tag: u32,
    union {
        unsigned: u8,
        signed: i16,
    },
}
```

And the representation of (u64 | []u8) is equivalent to

```c
struct {
    pad: u32,
    tag: u32,
    union {
        unsigned: u64,
        slice: []u8,
    },
}
```

6.5.17.3 The tag value shall be the type ID of the type which is selected from the constituent types. This value shall be stored at the u32 field and shall indicate which type is stored in the value area.

6.5.17.4 The alignment of a tagged union type shall be the alignment of the u32 type or the maximum alignment of the constituent types, whichever is greater.

6.5.17.5 The size of a tagged union type shall be the maximum size of its constituent types, plus the size of the u32 type, plus any padding added per «6.5.17: Tagged union types».

6.5.17.6 If a member type among tagged-types is a tagged union type, it shall be reduced such that nested tagged union type is replaced with its constituent types in the parent union.

The types (A | (B | (C | D))) and (A | B | C | D) are equivalent.

6.5.17.7 The default value of a tagged union type is undefined.

6.5.17.8 A tagged union type shall be equivalent to another tagged union type if they share the same set of secondary types, without regard to order, and considering the secondary types of nested tagged unions as members of the set of their parent’s secondary types.

It follows that the types (A | B) and (B | A) are equivalent.
6.5.18 Slice and array types

slice-array-type:

[ ] type
[ expression ] type
[ * ] type
[ – ] type

6.5.18.1 An array type stores one or more items of a uniform secondary type. The number of items stored in an array type is an attribute of the array type and is specified during the translation phase. The secondary type shall have a definite, non-zero size.

6.5.18.2 The expression representation is used for array types of a determinate length, that is, with a determinate number of items. Such arrays are bounded. The expression must evaluate to a positive integer value, and shall be limited to the «6.8: Translation compatible expression subset».

6.5.18.3 An array type may be unbounded, in which case the number of items is not known. The * representation indicates an array of this type.

6.5.18.4 An array may be bounded, but infer its size from context, using the – representation. Such an array is said to be context-defined.

6.5.18.5 An array type may be expandable. This state is not represented in the type grammar, and is only used in specific situations. Array types are presumed to be non-expandable unless otherwise specified.

6.5.18.6 The representation of an array type shall be the items concatenated one after another, such that the offset of the Nth item is determined by the equation $N \times S$, where $S$ is the size of the secondary type.

6.5.18.7 A slice type stores a pointer to an unbounded array type, with a given capacity, and length, which respectively refer to the number of items that the unbounded array may store without re-allocation, and the number of items which are currently valid. The representation with no lexical elements between [ and ] indicates a slice type.

6.5.18.8 The representation of a slice type shall be equivalent to the following struct type:

```c
struct {
  data: nullable *[*]type,
  length: size,
  capacity: size,
}
```

The type of the data field shall be a nullable pointer to an unbounded array of the secondary type.

6.5.18.9 The alignment of an array type shall be equivalent to the alignment of the underlying type. The alignment of a slice type shall be equivalent to the alignment of the size type or «6.5.13: Pointer types», whichever is greater.
6.5.18.10 The size of a bounded array type shall be equal to \( N \times S \), where \( N \) is the number of items and \( S \) is the size of the underlying type. The size of an unbounded array is undefined. The size of a slice type shall be equal to the size of the struct type defined by \( \langle 6.5.18 \rangle \): Slice and array types.

6.5.18.11 The default value of an array type shall be equal to all of its members set to the default value of the underlying type. If the default value of the underlying type is undefined, the default value of the array type is undefined.

6.5.18.12 The default value of a slice type shall have the capacity and length fields set to zero and the data field set to null.

6.5.18.13 An array type shall be equivalent to another array type only if its length and secondary types are equivalent. A slice type shall only be equivalent to a slice type with the same secondary type.

6.5.19 String types

\( \text{string-type: str} \)

6.5.19.1 A string stores a reference to a sequence of Unicode codepoints, encoded as UTF-8, along with its \textit{length} and \textit{capacity}. The length and capacity are measured in octets, rather than codepoints.

6.5.19.2 The representation of the string type shall be equivalent to the following struct type:

```rust
struct {
    data: nullable *[*]const u8,
    length: size,
    capacity: size,
}
```

6.5.19.3 The default value of a string type shall have the length field set to zero and the data field set to null.
6.5.20 Function types

function-type:
    fntype-attr_opt fn prototype

prototype:
    ( parameter-list_opt ) type

fntype-attr:
    @noreturn

parameter-list:
    parameters_opt
    parameters ... , opt
    parameters , ... , opt
    ... , opt

parameters:
    parameter
    parameters , parameter

parameter:
    name : type
    type

6.5.20.1 Function types represent a procedure which may be completed in the «5.4: Execution environment» to obtain a result and possibly cause side effects (see «5.4.6.1: Program execution»).

6.5.20.2 If the @noreturn form of fntype-attr is specified in the function-parameters, the type shall be void and the specified function shall not return to its caller. If the end of the function is reached in the execution environment, a diagnostic message shall be printed and the execution environment shall abort.

6.5.20.3 The attributes of a function type are its result type and input parameters. A function type must have one result type (which may be void), and zero or more parameters. Each name shall be unique.

6.5.20.4 If the second form of parameter-list is used, the final parameter of the function type uses Hare-style variadism. If the third or fourth form is used, the function uses C-style variadism. The variadism of a function type affects the calling semantics for that function.

// Hare-style variadism:
fn(x: int, y: int, z: int...)

// C-style variadism:
fn(x: int, y: int, ...)

Forward references: «6.6.24 Calls»
6.5.20.5 The implementation is not required to support C-style variadism. If the implementation does not support C-style variadism, it must print a diagnostic message and abort the translation environment for programs which attempt to utilize it.

6.5.20.6 The type of a parameter which uses Hare-style variadism shall be a slice of the specified type.

Therefore, in the case of fn(x: int...), the type of x shall be const [ ]int.

6.5.20.7 The size, alignment, default value, and storage semantics of function types is undefined. All function types shall be const, without regard to the use of const in the type description.

6.5.20.8 The function’s result type, list of parameter types (in order), its variadism, and @noreturn status, are distinct characteristics of the function type, for the purpose of determining equivalency.

6.5.21 Type aliases

alias-type:
    identifier

unwrapped-alias:
    ... identifier

6.5.21.1 A type alias assigns an identifier a unique type which is an alias for another type or a name for a set of enum values.

The grammar for an alias-type does not specify the underlying type. The underlying type is specified at the time it is declared, see «6.11: Declarations».

6.5.21.2 A type alias shall have the same storage, alignment, size, and semantics as its underlying type.

6.5.21.3 A type alias that represents an enum type shall have a default value of zero only if one of the enum values is equal to zero, otherwise its default value is undefined. A type alias that doesn’t represent an enum type shall have the same default value as its underlying type.

6.5.21.4 Each type alias (uniquely identified by its identifier) shall be a unique type, even if it shares its underlying type with another type alias.

6.5.21.5 The ... operator shall unwrap the type alias, and shall cause the statement to refer to the underlying type rather than the type alias itself.

This notably affects the relationship between type aliases and tagged unions. In the following example, union_a and union_b have different storage semantics, the former being a tagged union of two other tagged unions, and the latter being reduced to a single tagged union.

type signed = (i8 | i16 | i32 | i64 | int);
type unsigned = (u8 | u16 | u32 | u64 | uint);
type union_a = (signed | unsigned);
type union_b = (...signed | ...unsigned);

6.6 Expressions

6.6.1 An expression is a procedure which the implementation may perform to obtain a result, and possibly cause side-effects (see «5.4.6.1: Program execution»).

6.6.2 Expression types are organized into a number of classes and subclasses of expressions which define the contexts in which each expression type is applicable.

6.6.3 All expressions have a defined result type. It may be void.

6.6.4 Some expressions terminate. The semantics of terminating expressions vary between different expression types, and will be detailed as appropriate. If unspecified, expressions described by this expression are presumed to be non-terminating. Expression classes inherit their termination qualities from the more specific sub-expressions which they classify.

6.6.5 Some expressions may provide a type hint to other expressions which appear in their grammar, which those expressions may take advantage of to refine their behavior.

6.6.6 Constants

constant:
    integer-constant
    floating-constant
    rune-constant
    string-constant
    true
    false
    null
    void

6.6.6.1 Constants (also known as literals) describe a specific value of an unambiguous type. The result of the expression is the constant value.

6.6.6.2 The keywords true and false respectively represent the constants of the bool type.

6.6.6.3 The representation of true as an uint-equivalent (ref «6.5.14: Other primitive types») shall be one.

6.6.6.4 The null keyword represents the null value of the null type.

6.6.6.5 The void keyword represents the void value of the void type.
6.6.7 Floating constants

TTYUZU}

6.6.7 Floating constants

floating-constant: exactly:
  decimal-digits . decimal-digits exponent_opt floating-suffix_opt
  decimal-digits exponent_opt floating-suffix

floating-suffix: one of:
  f32 f64

decimal-digits: exactly:
  decimal-digit decimal-digits_opt

decimal-digit: one of:
  0 1 2 3 4 5 6 7 8 9

exponent: exactly:
  exponent-char sign_opt decimal-digits

sign: one of:
  + -

exponent-char: one of:
  e E

Floating constants represent an approximation to a real number.

6.6.8 If the floating-suffix is not provided, the result shall be fconst. Otherwise, the type shall refer to the type named by the suffix.

6.6.9 If the part before the decimal point is equal to zero, it shall be written as a single digit number. If the part before the decimal point is not equal to zero, it shall not begin with the digit 0.

6.6.10 If the exponent is provided, the value of the constant shall be multiplied by 10 to the power of decimal-digits. If sign is provided within the exponent, decimal-digits shall assume the given sign.
6.6.11 Integer constants

integer-constant: exactly:
   0x hex-digits integer-suffix\textsubscript{opt}
   0o octal-digits integer-suffix\textsubscript{opt}
   0b binary-digits integer-suffix\textsubscript{opt}
   decimal-digits exponent\textsubscript{opt} integer-suffix\textsubscript{opt}

hex-digits: exactly:
   hex-digit hex-digits\textsubscript{opt}

hex-digit: one of:
   0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f

octal-digits: exactly:
   octal-digit octal-digits\textsubscript{opt}

octal-digit: one of:
   0 1 2 3 4 5 6 7

binary-digits: exactly:
   binary-digit binary-digits\textsubscript{opt}

binary-digit: one of:
   0 1

integer-suffix: one of:
   i u z i8 i16 i32 i64 u8 u16 u32 u64

Integer constants represent an integer value at a specific precision.

6.6.12 If the integer-suffix is provided, the type is specified by the suffix. Suffixes \texttt{i}, \texttt{u}, and \texttt{z} shall respectively refer to the \texttt{int}, \texttt{uint}, and \texttt{size} types; the remainder shall refer to the type named by the suffix. Otherwise, the type shall be \texttt{iconst} with both maximum and minimum set to the number provided.

6.6.13 If the number provided is not within the limits of the precision of the constant type, a diagnostic message shall be printed and the translation phase shall fail.

6.6.14 The prefixes \texttt{0x}, \texttt{0o}, and \texttt{0b} shall respectively cause the number to be interpreted with a hexadecimal, octal, or binary base. If no prefix is used, the number shall be interpreted with a decimal base. In decimal base, zero shall be written as a single digit number. Numbers other than zero that are given in decimal base shall not begin with the digit \texttt{0}. \texttt{hex-digits} shall be interpreted in a case-insensitive manner.

6.6.15 If the exponent is provided, the value of the integer shall be multiplied by 10 to the power of decimal-digits. If sign is provided and is negative (-), a diagnostic message shall be printed and the translation phase shall abort.
6.6.16 Rune constants

rune-constant: exactly:
   ' rune '

rune:
   Any character other than \ or ' 
   escape-sequence

escape-sequence: exactly:
   named-escape
   \x hex-digit hex-digit
   \u fourbyte
   \U eightbyte

fourbyte: exactly:
   hex-digit hex-digit hex-digit hex-digit

eightbyte: exactly:
   fourbyte fourbyte

named-escape: one of:
   \0 \a \b \f \n \r \t \v \" \' \" \'

6.6.16.1 A rune-constant shall have a result type of rconst.
6.6.16.2 If the rune-constant is not an escape-sequence, the value of the rune shall be the Unicode codepoint representing rune.
6.6.16.3 A rune-constant beginning with \x, \u, or \U shall interpret its value as a Unicode codepoint specified in its hexadecimal representation by hex-digits.
6.6.16.4 A rune-constant containing a named-escape shall have a value based on the following chart:

<table>
<thead>
<tr>
<th>Escape sequence</th>
<th>Unicode codepoint</th>
<th>Escape sequence</th>
<th>Unicode codepoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>\0</td>
<td>U+0000</td>
<td>\a</td>
<td>U+0007</td>
</tr>
<tr>
<td>\b</td>
<td>U+0008</td>
<td>\f</td>
<td>U+000C</td>
</tr>
<tr>
<td>\n</td>
<td>U+000A</td>
<td>\r</td>
<td>U+000D</td>
</tr>
<tr>
<td>\t</td>
<td>U+0009</td>
<td>\v</td>
<td>U+000B</td>
</tr>
<tr>
<td>&quot;</td>
<td>U+005C</td>
<td>'</td>
<td>U+0027</td>
</tr>
<tr>
<td>&quot;</td>
<td>U+0022</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
6.6.17 String constants

```
string-constant:
  string-section  string-constant_opt

string-section: exactly:
  "  string-chars_opt  "
  `  rawstring-chars_opt  `

string-chars: exactly:
  string-char  string-chars_opt

string-char:
  Any character other than \ or "
  escape-sequence

rawstring-chars: exactly:
  rawstring-char  rawstring-chars_opt

rawstring-char:
  Any character other than `.
```

6.6.17.1 A string-constant expression shall have a result type of `const str`.

6.6.17.2 If the first form of string-section is used, the string’s `data` field shall refer to a UTF-8 encoded sequence of Unicode codepoints, ascertained by encoding the sequence of string-chars given in order, after interpreting escape codes per «6.6.16: Rune constants».

6.6.17.3 If the second form of string-section is used, the string’s `data` field shall refer to a UTF-8 encoded sequence of Unicode codepoints, ascertained by encoding the sequence of rawstring-chars given in order.

6.6.17.4 If a string-constant consists of more than one string-section, the string’s `data` field shall refer to a UTF-8 encoded sequence of Unicode codepoints, ascertained by concatenating the `data` fields of the string-sections given in order.

6.6.17.5 The `length` and `capacity` fields shall be set to the length in octets of the encoded UTF-8 data.

6.6.18 Array literals

```
array-literal:
  [  array-members_opt  ]

array-members:
  expression , opt
  expression ... , opt
  expression , array-members
```
6.6.18.1 An array-literal expression produces a value of an array type. The type of each expression shall be uniform and shall determine the member type of the array value, and the length of the array type shall be defined by the number of members.

6.6.18.2 If a type hint has been provided to an array literal which is an array type (or a type alias which represents an array type), the member type will be inferred from this array type. The initializer expressions for each value among array-members shall receive this member type as a type hint. If the array-members is not specified, a type hint must be provided.

6.6.18.3 The array-members shall be evaluated in the order in which they appear in the array-literal, and the Nth item shall provide the value for the Nth array member.

6.6.18.4 If the ... form is used, the result’s array type shall be expandable. If a type hint is available, it shall not be of a context-defined array type.

6.6.19 Struct literals

struct-literal:

\[
\text{struct} \\{ \text{field-values} \sideset{_{\text{opt}}}{,} \text{opt} \}\]

identifier \{ struct-initializer \sideset{_{\text{opt}}}{,} \text{opt} \}

struct-initializer:

field-values

\[
\text{field-values} \sideset{_{,}}{,} \ldots
\]

field-values:

field-value

\[
\text{field-values} \sideset{_{,}}{,} \text{field-value}
\]

field-value:

\[
\text{name} = \text{expression}\\
\text{name} : \text{type} = \text{expression}\\
\text{struct-literal}
\]

6.6.19.1 A struct-literal produces a value of a struct type. The first form is the plain form, and the second form is the named form.

6.6.19.2 If the plain form is given, the result type shall be a struct type defined by the field-values, in order, with their identifiers and types explicitly specified. The first form of field-value shall not be used in such a struct.

6.6.19.3 If the named form is given, the identifier shall identify a type alias (see Type aliases) which refers to a struct or union type. The result type shall be this alias type.

6.6.19.4 Each field-value shall specify a field by its name, and assign that field in the result value to the result of the expression given. The type of the named field, via the
named type alias in the first form, or the given type in the second form, shall be provided to the initializer expression as a type hint. The field-values shall be evaluated in the order in which they appear in the struct-literal.

6.6.19.5 If ... is not given, field-values shall be exhaustive, and include every field of the result type exactly once. Otherwise, a diagnostic message shall be printed and the translation phase shall abort.

6.6.19.6 If ... is given, any fields of the result type which are not included in field-values shall be initialized to their default values. Each included field shall only be named once. If a field is omitted which does not have a default value, a diagnostic message shall be printed and the translation phase shall abort.

6.6.19.7 If the named type is a union type, the field-values shall be empty and ... provided. The union type must have a default value.

6.6.19.8 If the struct-literal form of the field-value is given, its fields shall be interpreted as fields of the parent struct. The following values are equivalent:

```plaintext
struct { a: int = 10, b: int = 20 }
struct { a: int = 10, struct { b: int = 20 } }
```

6.6.20 Tuple literals

tuple-literal:

```
( tuple-items )
```

tuple-items:

```
expression , expression , opt
expression , tuple-items
```

6.6.20.1 A tuple-literal produces a value of a tuple type. The result type shall be the tuple type described by the types of its expressions in the order that they appear.

6.6.20.2 If a type hint is available and the hint is a tuple type (or a type alias which represents a tuple type), the tuple items shall receive as hints the types of the respective tuple sub-types in the order that they appear.

6.6.20.3 The tuple-items shall be evaluated in the order in which they appear in the tuple-literal, and the Nth item shall provide the value for the Nth tuple item.
6.6.21 Plain expressions

plain-expression:
  identifier
  constant
  array-literal
  struct-literal
  tuple-literal

nested-expression:
  plain-expression
  ( expression )

6.6.21.1 plain-expression is an expression class which represents its result value "plainly". In the case of constants and literals, the value is represented by the result of those expressions. In the case of an identifier, the expression produces the value of the identified object.

6.6.21.2 nested-expression is an expression class provided to allow the programmer to overcome undesirable associativity between operators.

6.6.22 Allocations

allocation-expression:
  alloc ( expression )
  alloc ( expression ... )
  alloc ( expression , expression )
  free ( expression )

6.6.22.1 An alloc expression allocates an object at runtime and initializes its value to the first expression (the initializer). The result type of the initializer provides the allocation's object type. The result type of the allocation expression is, usually, a pointer type whose secondary type is the object type.

6.6.22.2 The first form is the object allocation form. If the allocation expression is provided a type hint of a pointer type, the secondary type of this pointer type shall be provided to the initializer as its type hint. The execution environment will allocate sufficient storage for the object type and initialize its value using the initializer expression, then set its result to a pointer to the new object. The object type must have a defined size which is greater than zero.

6.6.22.3 The second form is the copy allocation form. In this form, the initializer will provide an object type which is either a slice or array type (or an alias thereof). The execution environment will allocate storage sufficient to store an array equal in length to the initializer, then copy the initializer’s slice or array items into this array. The result value shall be set to a slice object whose secondary type is equal to the secondary type of the initializer’s result type, whose data field refers to the new array, and whose length and capacity fields are set to the length of the array.
6.6.22.4 The third form is the slice allocation form. In this form, the initializer will be assignable to a slice or array type, and the second expression provides the desired capacity for a new slice. The capacity shall be assignable to the size type. The execution environment shall choose a capacity equal to or greater than this term, then provision an array of that length and set each \( N \)th value to the \( N \)th value of the initializer, for each value of \( N \) between 0 (inclusive) and the length of the initializer (exclusive). The result of the allocation-expression shall be a slice whose data field refers to this array, whose length is equal to the length of the initializer, and whose capacity is set to the selected capacity.

6.6.22.5 In the slice allocation form, if the array specified by the initializer is expandable, the second expression shall be used as the length instead of the capacity. The execution environment shall choose a capacity equal to or greater than this value, then for each \( N \)th value of the allocated array from the length of the initializer \( (L, \text{inclusive}) \) to the specified length \( (L') \) shall be initialized to the value at \( L - 1 \) in the initializer. The length field of the resulting slice value shall be set to the \( L' \).

The following allocates a slice of length 10 with all values set to zero:

```
let x: []int = alloc([0...], 10)
```

6.6.22.6 In the alloc form, if the execution environment is unable to allocate sufficient storage for the requested type, the execution environment shall print a diagnostic message and abort. If the type hint is a nullable pointer type, the result type of the allocation expression shall also be nullable, and null shall be returned instead of aborting if sufficient storage cannot be provided.

6.6.22.7 The free form shall discard resources previously allocated with a alloc expression, freeing them for future use. The expression shall evaluate to a pointer type, in which case the object referred to by the pointer shall be freed, or a slice type, in which case the array referred to by its data field shall be freed.

6.6.23 Assertions

```
assertion-expression:
  static\_opt assert ( expression )
  static\_opt assert ( expression , expression )
  static\_opt abort ( expression\_opt )
```

6.6.23.1 An assertion-expression is used to validate an assumption by the programmer by asserting its truth. The result type of an assertion-expression is void.

6.6.23.2 In the first two forms, if static is omitted, the first expression shall be evaluated in the execution environment. If the expression evaluates to false, a diagnostic message shall be printed and the execution phase aborted. The expression shall have type bool, which shall be provided to it as a type hint.

6.6.23.3 In the second assert form, and in the abort form if present, the final expression shall have type str, which shall be provided to it as a type hint. The contents of the string shall be included in the diagnostic message.

6.6.23.4 In the abort form, if static is omitted, the execution environment shall uncondi-
tionally print a diagnostic message and abort.

6.6.23.5 If `static` is given, behavior is identical to when `static` is omitted, except that the assertion is run in the translation environment rather than the execution environment.

### 6.6.24 Calls

**call-expression:**

```
call-expression:  
    postfix-expression  (  argument-listopt  )
```

**argument-list:**

```
argument-list:  
    expression   ,opt  
    expression   ... ,opt  
    expression , argument-list
```

6.6.24.1 A `call-expression` shall invoke a function in the execution environment and its result shall be a value of the type specified by the `postfix-expression`’s function result type. This evaluation shall include any necessary side-effects per §5.4.6.1: Program execution».

6.6.24.2 The result type of the `postfix-expression` shall be restricted to a set which includes all function types which do not have the `@init`, `@fini`, or `@test` attributes set, as well as non-nullable pointers whose secondary type is included in the set.

*The result type of the `postfix-expression` can be a function, a pointer to a function, a pointer to a pointer to a function, and so on.*

6.6.24.3 The function invoked shall be the function object the `postfix-expression` refers to, selecting that object indirectly via any number of pointer types if appropriate.

6.6.24.4 The `argument-list` shall be a list of expressions whose types shall be assignable to the types of the invoked function’s parameters, in the order that they are declared in the invoked function’s result type. The types specified in the function’s prototype shall be provided as type hints to each argument expression as appropriate.

6.6.24.5 The execution environment shall evaluate the `argument-list`, ordered such that any side-effects of evaluating the arguments occur in the order that the arguments are listed, to obtain the parameter values required to invoke the function.

6.6.24.6 If the invoked function uses Hare-style variadism, the `argument-list` shall provide zero or more arguments following the last non-variadic parameter, all of which must be assignable to the type of the variadic parameter.

6.6.24.7 If the final argument uses the `...` form, it must occupy the position of a variadic parameter and be of a slice or array type. The implementation shall interpret this value as the list of variadic parameters.

6.6.24.8 If the invoked function uses C-style variadism, the function may provide zero or more arguments following the final parameter. These arguments shall be of a type with a non-zero size, but are otherwise unconstrained.

6.6.24.9 The specific means by which the invoked function assumes control of the execution
environment, and by which the arguments are provided to it, is implementation-defined.

This is generally provided by the target’s ABI specification.

6.6.24.10 If the invoked function’s result type has the @noreturn attribute, the call expression is considered to terminate.

6.6.25 Measurements

measurement-expression:
  align-expression
  size-expression
  length-expression
  offset-expression

align-expression:
  align ( type )

size-expression:
  size ( type )

length-expression:
  len ( expression )

offset-expression:
  offset ( field-access-expression )

Forward references: «6.6.26: Field access»

6.6.25.1 A measurement-expression is used to measure objects. The result type shall be size.

6.6.25.2 The align expression shall compute the alignment of the specified type. If type is a type of undefined alignment of a type of size 0, a diagnostic message shall be printed and translation shall abort.

6.6.25.3 The size expression shall compute the size of the specified type. If type is a type of undefined size, a diagnostic message shall be printed and translation shall abort.

6.6.25.4 The len expression shall compute the length of a bounded array, the length field of a slice object, or the length field of a str, referred to by expression. If an unbounded array object is given, the translation environment shall print a diagnostic message and abort.

6.6.25.5 The object used for a length expression shall be the array, slice, or str object the expression refers to, selecting that object indirectly via any number of non-nullable pointer types if appropriate.

6.6.25.6 The offset expression shall determine the struct or tuple field which would be accessed by field-access-expression and compute its offset.
6.6.26 Field access

\[ \text{field-access-expression:} \]
\[ \text{postfix-expression . name} \]
\[ \text{postfix-expression . integer-constant} \]

6.6.26.1 A field-access-expression is used to access fields of \([6.5.15]\) Struct and union types» and \([6.5.16]\) Tuple types». The result type of the postfix-expression shall be constrained to a set which includes all struct, union, and tuple types, as well as non-nullable pointers whose secondary type is included in the set.

The result type of the postfix-expression can be a struct or union or tuple, a pointer to a struct or union or tuple, a pointer to a pointer to a struct or union or tuple, and so on.

6.6.26.2 The object from which the field is selected shall be the struct or union object the postfix-expression refers to, selecting that object indirectly via any number of pointer types if appropriate.

6.6.26.3 If the postfix-expression’s result type is a union type, the first form shall be used. The result of the field-access-expression shall be the union’s storage area interpreted as the type of the field named by name, and the result type of the expression shall be the type of the named field.

6.6.26.4 If the postfix-expression’s result type is a struct type, the first form shall be used. The result of the field-access-expression shall be the value stored in the name field of the result of the postfix-expression, and the result type of the expression shall be the type of the named field.

6.6.26.5 If the postfix-expression’s result type is a tuple type, the second form shall be used. The result of the field-access-expression shall be the \[N\]th value stored in the tuple which is the result of the postfix-expression, and the result type of the expression shall be the type of the \[N\]th value.

6.6.26.6 If the type of the struct object in the first term has the const flag, the result type shall also have the const flag set, regardless of the flag’s value on the type of the named field.

6.6.27 Indexing

\[ \text{indexing-expression:} \]
\[ \text{postfix-expression [ expression ]} \]

6.6.27.1 An indexing-expression shall access a specific value of a slice or array type. The expression shall have an integer result type. The result type of the postfix-expression shall be constrained to a set which includes all slice and array types, as well as non-nullable pointers whose secondary type is included in the set.

The result type of the postfix-expression can be a slice or array, a pointer to a slice or array, a pointer to a pointer to a slice or array, and so on.
6.6.27.2 The object from which the field is selected shall be the slice or array object the \texttt{postfix-expression} refers to, selecting that object indirectly via any number of pointer types if appropriate.

6.6.27.3 The result type of an \texttt{indexing-expression} is the secondary type of the slice or array type given by the \texttt{postfix-expression} result type.

6.6.27.4 If the type of the array or slice object in the first term has the \texttt{const} flag, the result type shall also have the \texttt{const} flag set, regardless of the flag's value on the secondary type.

6.6.27.5 The execution environment shall compute the result of \texttt{expression} to obtain \( N \) for selecting the \( N \) per the algorithm given in «6.5.18: Slice and array types».

6.6.27.6 The execution environment shall perform a \texttt{bounds test} on the value of \( N \) to ensure it falls within the acceptable range for the given slice or array type. It shall test that \( N < Z \), where \( Z \) is the length of the bounded array type, or the \texttt{length} field of the slice, whichever is appropriate. For unbounded array types, the bounds test shall not occur. If the bounds test fails, a diagnostic message shall be printed and the execution environment shall abort.

The implementation may perform a bounds test in the translation environment if it is able, and print a diagnostic message and abort the translation environment if it fails.

6.6.28 Slicing

\texttt{slicing-expression:}
\begin{verbatim}
  postfix-expression [ expression_{opt} .. expression_{opt} ]
\end{verbatim}

6.6.28.1 A \texttt{slicing-expression} shall have a result type of \texttt{slice}, which is computed a subset of a slice or array object. The optional \texttt{expressions} shall have an integer result type. The result type of the \texttt{postfix-expression} shall be constrained to a set which includes all slice and array types, as well as non-nullable pointers whose secondary type is included in the set.

\textit{The result type of the \texttt{postfix-expression} can be a slice or array, a pointer to a slice or array, a pointer to a pointer to a slice or array, and so on.}

6.6.28.2 The object from which the field is selected shall be the slice or array object the \texttt{postfix-expression} refers to, selecting that object indirectly via any number of pointer types if appropriate.

6.6.28.3 The first \texttt{expression} shall compute value \( L \), and the second shall compute \( H \). If absent, \( L = 0 \) and \( H = \texttt{length} \), where \texttt{length} shall be equal to the length of a bounded array type or the length of a slice type, represented in either case by the result of \texttt{postfix-expression}. If \( H \) is not specified, and \texttt{postfix-expression} is of an unbounded array type, the translation environment shall abort.

6.6.28.4 The resulting slice value shall have its \texttt{data} field set from, in the case of an array type, the address of the array; or in the case of a slice type, the \texttt{data} value of the source object; plus \( L \times S \), where \( S \) is the size of the slice or array’s secondary type.
6.6.28.5 The resulting slice value shall have its \texttt{length} field set to $H - L$, and its capacity field set to the \texttt{length} of the source object minus $L$. If the length of the object is undefined, the capacity shall be set to $H - L$ instead.

6.6.28.6 The secondary type of the resulting slice type shall be equivalent to the secondary type of the slice or array type given by postfix-expression. The resulting slice type shall inherit the \texttt{const} attribute from this type.

### 6.6.29 Appending

\texttt{slice-mutation-expression}:
\begin{align*}
\texttt{append-expression} \\
\texttt{insert-expression} \\
\texttt{delete-expression}
\end{align*}

\begin{align*}
\texttt{append-expression}:
\begin{align*}
\texttt{static}_{\textit{opt}} \quad \texttt{append} \quad (\quad \texttt{object-selector} \quad , \quad \texttt{expression} \quad ) \\
\texttt{static}_{\textit{opt}} \quad \texttt{append} \quad (\quad \texttt{object-selector} \quad , \quad \texttt{expression} \quad \ldots \quad ) \\
\texttt{static}_{\textit{opt}} \quad \texttt{append} \quad (\quad \texttt{object-selector} \quad , \quad \texttt{expression} \quad , \quad \texttt{expression} \quad )
\end{align*}
\end{align*}

6.6.29.1 An \texttt{append-expression} shall append a value, or values, to the slice object specified by the first argument. Valid result types for \texttt{object-selector} shall either be a slice type, or a non-nullable pointer to a valid result type. The selected object shall be mutable and non-const. The member type of this slice shall be the expression’s \texttt{member type}. The result of an \texttt{append} shall be \texttt{void}.

6.6.29.2 The second term of an \texttt{append} expression is the \texttt{append values}. In the first form, the \texttt{append values} shall specify a single value whose type is assignable to the member type. In the second form, the expression shall have a valid result type which shall be an array or slice whose member type is the append expression’s member type, or a non-nullable pointer to a valid result type.

6.6.29.3 The execution environment shall ensure that the capacity of the object is at least $N \geq L^1 + L^2$, where $L^1$ is the object length and $L^2$ is the length of the append values, reallocating the underlying storage if necessary. If sufficient storage cannot be allocated, the execution environment shall print a diagnostic message and abort. The length of the object shall be set to $L^1 + L^2$.

6.6.29.4 The third form of an \texttt{append-expression} shall specify an expandable array as its second term, and its third term shall be assignable to \texttt{size}. This form shall behave similarly to the second form, except that the new length and capacity of the object is given by the third term.

6.6.29.5 The execution environment shall assign values of the object slice from index $N = L^1$ (inclusive) to $N = L^1 + L^2$ (exclusive) from each append values at index $N - L^1$. In the third form of \texttt{append-expression}, the last value of append values shall be assigned for values $N = L^1 + L^2$ (inclusive) up to the index given by the third term (exclusive).

6.6.29.6 The \texttt{static} forms shall be equivalent to the non-static forms except that they shall
never cause the underlying slice to be reallocated. If the operation would require 
more space than the capacity of the slice provides, the execution environment shall 
print a diagnostic message and abort.

6.6.29.7 The side-effects shall occur in the following order: object-selector; then the length 
term, if present; then the append values.

6.6.29.8 The object selector shall not be provided a type hint. If ... is used, the append 
values shall be given the object type as its type hint; if not, it shall receive the 
member type as its type hint. The length will receive a type hint of size if 
applicable.

6.6.30 Inserting

insert-expression:

\[
\text{static}_{\text{opt}} \text{ insert} \ ( \text{indexing-expression} \ , \ \text{expression} ) \\
\text{static}_{\text{opt}} \text{ insert} \ ( \text{indexing-expression} \ , \ \text{expression} \ldots )
\]

6.6.30.1 An insert-expression shall insert a value, or values, into the slice object specified by 
the first argument. The indexing-expression specifies both the slice object and an 
index at which the new values shall be inserted (the insertion index). The selected 
object shall be mutable and non-const. The member type of this slice shall be the 
expression’s member type. The result of an insert shall be void.

6.6.30.2 The second term of an insert expression is the insert values. In the first form, the 
insert values shall specify a single value whose type is assignable to the member 
type. In the second form, the expression shall have a valid result type which shall 
be an array or slice whose member type is the insert expression’s member type, or 
a non-nullable pointer to a valid result type.

6.6.30.3 The execution environment shall ensure that the capacity of the object is at least 
\( N \geq L_1 + L_2 \), where \( L_1 \) is the object length and \( L_2 \) is the length of the insert 
values, reallocating the underlying storage if necessary. If sufficient storage cannot 
be allocated, the execution environment shall print a diagnostic message and abort. 
The length of the object shall be set to \( L_1 + L_2 \).

6.6.30.4 After ensuring sufficient space is available for the new items, the execution en-
vironment shall copy or move each item \( N \) such that from \( N = I \) (inclusive) to 
\( N = I + L_2 \) (exclusive), each item is placed at \( I + L_2 + N - 1 \), causing the items 
to "shift" over to accomodate the insert values.

6.6.30.5 The execution environment shall assign values of the object slice from index \( N = I \) 
(inclusive) to \( N = I + L_2 \) (exclusive) from each insert value in order.

6.6.30.6 The static forms shall be equivalent to the non-static forms except that they shall 
ever cause the underlying slice to be reallocated. If the operation would require 
more space than the capacity of the slice provides, the execution environment shall 
print a diagnostic message and abort.

6.6.30.7 The side-effects of the indexing-expression shall occur before the side-effects of 
the insert values.
6.6.30.8 The object selector shall be not be provided a type hint. If ... is used, the insert values shall be given the object type as its type hint; if not, it shall receive the member type as its type hint. The length will receive a type hint of size if applicable.

6.6.31 Deleting

delete-expression:

\[ \text{static}_{\text{opt}} \text{ delete} ( \text{indexing-expression} ) \]

\[ \text{static}_{\text{opt}} \text{ delete} ( \text{slicing-expression} ) \]

6.6.31.1 A delete-expression shall remove a value, or values, from the slice object specified by the first argument. The selected object shall be mutable and non-const. The result of a delete shall be void.

6.6.31.2 Should a indexing-expression be used, it shall specify the index of a single value as the deleted items. Should a slicing-expression be used, it shall specify a range of values as the deleted items.

6.6.31.3 The execution environment shall set the length of the slice object to \( L^1 - L^2 \), where \( L^1 \) is its previous length and \( L^2 \) is the number of deleted items. Starting from the first index specified by the indexing-expression or slicing-expression, \( I \), each item at index \( N + L^1 \) shall be copied to \( N \), "shifting" items over to reclaim the space previously used by the deleted items.

6.6.31.4 The execution environment may decrease the slice object's capacity, re-allocating its data field if necessary, in order to reclaim unused memory. This re-allocation, if performed, shall not fail. The slice object shall be updated to reflect the new capacity if necessary.

6.6.31.5 The static forms shall be equivalent to the non-static forms except that they shall never cause the underlying slice to be reallocated.

6.6.32 Error propagation

ererror-propagation:

\[ \text{postfix-expression} \ ? \]

\[ \text{postfix-expression} \ ! \]

6.6.32.1 ? and ! are the error propagation operators. The postfix-expression shall have a result type which is either a type with the error flag set, or a tagged union type which has a type with the error flag set among its member types.

6.6.32.2 The result type of an error propagation expression shall be the same as the type of the postfix-expression, without its error cases, or void if no non-error types remain. The result is a tagged union whose member types are the subset of the original type which do not include the error flag; or, if there is only one such type, that type without a tagged union; or, if there are no such types, void. If the original type is not a tagged union type, the translation phase shall abort with a diagnostic
message.

6.6.32.3 An error propagation expression shall perform an error test which checks if the result value of the postfix-expression is of a non-error type. If so, that value shall be the result of the error propagation expression.

6.6.32.4 In the ? form, if the error test fails (i.e. an error is found), the error type shall be assignable to the current function’s return type, and that value shall be returned from the function.

6.6.32.5 In the ! form, if the error test fails (i.e. an error is found), the execution environment shall print a diagnostic message and abort.

6.6.32.6 If a type hint is provided to the error propagation expression, the same type shall be provided to the postfix-expression.

6.6.33 Postfix expressions

postfix-expression:
  nested-expression
  call-expression
  field-access-expression
  indexing-expression
  slicing-expression
  error-propagation

object-selector:
  identifier
  indexing-expression
  field-access-expression

6.6.33.1 postfix-expression is an expression class for expressions whose operators use postfix notation.

6.6.33.2 object-selector defines a subset of postfix expressions which refer to objects, for use in other parts of the grammar.

6.6.34 Variadic expressions

variadic-expression:
  vastart ( )
  vaarg ( object-selector )
  vaend ( object-selector )

6.6.34.1 Variadic expressions are provided for compatibility with the C programming language as specified by ISO/IEC 9899:2011. Implementation support is optional: implementations which do not provide C ABI compatibility must parse these expressions, print a diagnostic message, and abort.
These expressions are used only for C compatibility. "Hare-style" variadism is handled separately.

6.6.34.2 The `vastart` expression shall have a result type of `valist`, and may only be used within a function body which uses C-style variadism. It will initialize a structure compatible with the "va_list" type defined by ISO/IEC 9899:2011 section 7.16.3 such that the first use of "va_arg" would return the first variadic parameter.

6.6.34.3 The `vaarg` expression accepts an `object-selector` which must be of the `valist` type. The expression shall also be provided a type hint. The result of the expression shall be the next variadic parameter from the `valist` object of the type provided by the type hint, and the object shall be advanced to the next parameter. This expression shall behave in a manner compatible with ISO/IEC 9899:2011 section 7.16.1.1’s "va_arg" macro. The result type of this expression is `void`.

6.6.34.4 The `vaend` expression accepts an `object-selector` which must be of the `valist` type. The implementation shall finalize the `valist` object in an implementation-defined manner which is compatible with ISO/IEC 9899:2011 section 7.16.1.2. The result type of this expression is `void`.

6.6.35 Built-in expressions

```
builtin-expression:
  allocation-expression
  assertion-expression
  measurement-expression
  slice-mutation-expression
  postfix-expression
  variadic-expression
```

6.6.36 Unary arithmetic

```
unary-expression:
  builtin-expression
  compound-expression
  match-expression
  switch-expression
  unary-operator unary-expression
```

```
unary-operator: one of:
  + - ~ ! * &
```

6.6.36.1 A unary expression applies a [unary-operator] to a single value.

6.6.36.2 The + and - operators shall respectively perform unary positive and unary negation operations. The result type shall be equivalent to the type of [unary-expression], which shall be of a numeric type.

6.6.36.3 The ~ operator shall perform a bitwise NOT operation, inverting each bit of the
value. Its result type shall be equivalent to the type of `unary-expression`, which shall be of an integer type.

6.6.36.4 The `!` operator shall perform a logical NOT operation. The result type, and the type of `unary-expression`, shall both be `bool`. If the `unary-expression` is `true`, the result shall be `false`, and vice-versa.

6.6.36.5 The `*` operator shall dereference a pointer, and return the object it references. The type of `unary-expression` shall be a pointer type, and the result type shall be the pointer’s secondary type. The pointer type shall not be `nullable`, and the pointer’s secondary type shall have a defined size.

6.6.36.6 The `&` operator shall take the address of an object. The result type shall be a pointer whose secondary type is the type of the object selected by the `unary-expression`. If the `unary-expression` is not an `object-selector`, the ensuing pointer shall only be valid within the current function.

### 6.6.37 Casts and type assertions

`cast-expression`:  
- `unary-expression`
- `cast-expression` : `type`
- `cast-expression as` `assertion-target`
- `cast-expression is` `assertion-target`

`assertion-target`:  
- `type`
- `null`

6.6.37.1 A cast expression interrogates or converts the type of an object. The first form illustrates the precedence. The second and third forms (`:` and `as`) have a result type specified by the `type`; and the fourth form (`is`) has a result type of `bool`.

6.6.37.2 Each form shall provide the specified `type` as a type hint to its `cast-expression`.

6.6.37.3 The second form is a `type cast`, and shall not fail. It shall cause the execution environment to convert or interpret the value as another type.

6.6.37.4 A type which may be cast to another type is considered *castable* to that type.

6.6.37.5 All types are castable to themselves. The set of other types which are castable to a given type are given by the following table:

6.6.37.6 The `cast-expression` being acted upon must not be a terminating expression.
<table>
<thead>
<tr>
<th>Result</th>
<th>Castable from</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any numeric type</td>
<td>Floating types</td>
</tr>
<tr>
<td>Any numeric type or enum type</td>
<td>Integer and enum types</td>
</tr>
<tr>
<td>Any pointer type or <code>null</code></td>
<td><code>uintptr</code></td>
</tr>
<tr>
<td>Any pointer type, <code>uintptr</code>, or <code>null</code></td>
<td>Any pointer type</td>
</tr>
<tr>
<td>Any array or slice type</td>
<td>Array types</td>
</tr>
<tr>
<td>Any slice type or pointer to an array type</td>
<td>Slice types</td>
</tr>
<tr>
<td>Any type the underlying type of the source could cast to</td>
<td>Type aliases</td>
</tr>
<tr>
<td>Any type alias with an underlying type the source may be cast to</td>
<td>Any type</td>
</tr>
<tr>
<td><code>u32</code> <code>rune</code></td>
<td><code>null</code></td>
</tr>
<tr>
<td>Any pointer type or <code>uintptr</code></td>
<td><code>Tagged unions</code></td>
</tr>
</tbody>
</table>

6.6.37.7 Tagged union types are mutually castable with any type which is found among its members, including otherwise non-castable types and other tagged union types.

6.6.37.8 When a flexible constant type is cast to another type, the «6.10: Flexible constant promotion algorithm» shall be applied to them, and the flexible constant shall be castable to the other type if the promotion succeeds.

6.6.37.9 When an integer type is cast to an integer of less precision, it shall be truncated towards the least significant bit.

6.6.37.10 When a signed type is cast to an unsigned type, the sign bit shall be copied to the most significant bit of the unsigned type, and vice versa.

6.6.37.11 When a floating type is cast to an integer, the resulting value shall be equal to the nearest integer with smaller or equal absolute value. If the destination type has insufficient precision to represent the resulting integer, it shall be truncated towards the least significant bit.

6.6.37.12 When casting an integer to a floating point type, if the destination type lacks the precision to represent the value, it shall be truncated towards zero.

6.6.37.13 Casting a pointer type to `uintptr`, and then back to the pointer type, shall yield the same pointer. Likewise, casting `null` to a `uintptr` and then back to a nullable pointer type shall yield `null`.

   However, casting `uintptr` to any other integer type and back again may truncate towards the least significant bit and is not guaranteed to yield the same pointer.

6.6.37.14 The `const` flag shall not affect the rules for casting one type to another. The same holds for the error flag as well.

6.6.37.15 The third form is a `type assertion`. In this form, `cast-expression` shall be of a tagged union type or a nullable pointer type.

   In the former case, `assertion-target` shall be `type` and shall be one of constituent types of type of that tagged union. The `cast-expression` shall be computed, and if the tag does not match `type`, a diagnostic message shall be printed and the execution environment shall abort. Otherwise, the result type is `type`.

   In the latter case `assertion-target` shall either be a `type` that is a nullable pointer type or `null`. If it is `null` and the value of `cast-expression` does not equal null,
a diagnostic message shall be printed and execution environment shall abort. If assertion-target is not null and the value of cast-expression equals null, a diagnostic message shall be printed and the execution environment shall abort. The result type of a type assertion with null as assertion-target shall be null. The result type of other type assertions shall be type.

6.6.37.16 The fourth form is a type test. In this form, the result type is bool, and shall be true if and only if the type assertion from cast-expression to assertion-target would succeed, or false otherwise.

6.6.38 Multiplicative arithmetic

\[
\text{multiplicative-expression}:
\]
\[
\text{cast-expression}
\]
\[
\text{multiplicative-expression} \ast \text{cast-expression}
\]
\[
\text{multiplicative-expression} / \text{cast-expression}
\]
\[
\text{multiplicative-expression} \% \text{cast-expression}
\]

6.6.38.1 A multiplicative-expression multiplies (\ast), divides (/), or obtains the remainder between (\%) two expressions. The first form illustrates the precedence. The operands and result type shall be subject to the «6.7: Type promotion» rules.

6.6.38.2 In the case of division or modulus, the first term is the dividend, and the second term is the divisor. The result of the modulus shall have the same sign as the dividend.

6.6.38.3 A modulus (\%) operation shall be performed with operands of integer types only.

6.6.38.4 If an operation would cause the result to overflow the result type, it is truncated towards the least significant bits in the case of integer types, and towards zero in the case of float types. Integer divisions which would produce a fractional part are rounded towards zero.

6.6.38.5 The implementation shall ensure that any side-effects of the first term shall occur before side-effects of the second term.

6.6.39 Additive arithmetic

\[
\text{additive-expression}:
\]
\[
\text{multiplicative-expression}
\]
\[
\text{additive-expression} + \text{multiplicative-expression}
\]
\[
\text{additive-expression} - \text{multiplicative-expression}
\]

6.6.39.1 An additive-expression adds (+) two operands, or subtracts (-) one from another. The first form illustrates the precedence. The operands and result type shall be subject to the «6.7: Type promotion» rules.

6.6.39.2 In the case of subtraction, the first term is the minuend, and the second term is the subtrahend.
6.6.39.3 If an operation would cause the result to overflow or underflow the result type, it is truncated towards the least significant bits in the case of integer types, and towards zero in the case of float types. In the case of signed types, this truncation will cause the sign bit to change.

6.6.39.4 The implementation shall ensure that any side-effects of the first term shall occur before side-effects of the second term.

6.6.40 Bit shifting arithmetic

\[
\text{shift-expression:} \\
\quad \text{additive-expression} \\
\quad \text{shift-expression} \ll \text{additive-expression} \\
\quad \text{shift-expression} \gg \text{additive-expression}
\]

6.6.40.1 A \textit{shift-expression} performs a bitwise left-shift (\texttt{\textless\textless}) or right-shift (\texttt{\textgreater\textgreater}). The first form illustrates the precedence. The result type shall be the type of the first operand. Both operands shall be of unsigned integer types.

6.6.40.2 \texttt{shift-expression} \ll \textit{N} shall shift each bit towards the most significant bit \textit{N} places, and set the least significant \textit{N} bits to zero. The \textit{N} most significant bits shall be silently discarded. If \textit{N} is greater than the size in bits of the type, the result shall be zero.

6.6.40.3 \texttt{shift-expression} \gg \textit{N} shall shift each bit towards the least significant bit \textit{N} places. The most significant bits shall be set to either zero or one depending on the signedness of \texttt{shift-expression}. If it is signed, then the \textit{N} most significant bits shall be set to the value of the sign bit. If it unsigned, then the \textit{N} most significant bits shall be set to zero. The \textit{N} least significant bits shall be silently discarded. If \textit{N} is greater than the size in bits of the type, the result shall be zero.

\textit{This operation is equivalent to dividing \texttt{shift-expression} by } 2^N

6.6.40.4 The implementation shall ensure that any side-effects of the first term shall occur before side-effects of the second term.

6.6.41 Bitwise arithmetic

\[
\text{and-expression:} \\
\quad \text{shift-expression} \\
\quad \text{and-expression} \& \text{ shift-expression}
\]

\[
\text{exclusive-or-expression:} \\
\quad \text{and-expression} \\
\quad \text{exclusive-or-expression} \quad ^\text{\&} \quad \text{and-expression}
\]

\[
\text{inclusive-or-expression:} \\
\quad \text{exclusive-or-expression} \\
\quad \text{inclusive-or-expression} \quad | \quad \text{exclusive-or-expression}
\]
6.6.41 An \textbf{and-expression} performs a bitwise and operation.
6.6.41.2 An \textbf{exclusive-or-expression} performs a bitwise exclusive or operation.
6.6.41.3 An \textbf{inclusive-or-expression} performs a bitwise inclusive or operation.
6.6.41.4 The operands and result type shall be subject to the \{6.7\}: Type promotion» rules.
6.6.41.5 The implementation shall ensure that any side-effects of the first term shall occur before side-effects of the second term.

6.6.42 \textbf{Logical comparisons}

\texttt{comparison-expression:}
\begin{itemize}
  \item \texttt{inclusive-or-expression}
  \item \texttt{comparison-expression < inclusive-or-expression}
  \item \texttt{comparison-expression > inclusive-or-expression}
  \item \texttt{comparison-expression <= inclusive-or-expression}
  \item \texttt{comparison-expression >= inclusive-or-expression}
\end{itemize}

\texttt{equality-expression:}
\begin{itemize}
  \item \texttt{comparison-expression}
  \item \texttt{equality-expression == comparison-expression}
  \item \texttt{equality-expression != comparison-expression}
\end{itemize}

6.6.42.1 A \texttt{comparison-expression} determines which operand is lesser than (<), greater than (>), less than or equal to (<=), or greater than or equal to (>=) the other. The operands shall be numeric, and are subject to the \{6.7\}: Type promotion» rules. The result type shall be \texttt{bool}.
6.6.42.2 The result of the \texttt{<} operator shall be \texttt{true} if the first operand is mathematically less than the second operand and \texttt{false} otherwise.
6.6.42.3 The result of the \texttt{>} operator shall be \texttt{true} if the first operand is mathematically greater than the second operand and \texttt{false} otherwise.
6.6.42.4 The result of the \texttt{<=} operator shall be \texttt{true} if the first operand is mathematically less than or equal to second operand and \texttt{false} otherwise.
6.6.42.5 The result of the \texttt{>=} operator shall be \texttt{true} if the first operand is mathematically greater than or equal to second operand and \texttt{false} otherwise.
6.6.42.6 An \texttt{equality-expression} determines if two operands are equal to one another. The result type is \texttt{bool}. If the types of the \texttt{==} or \texttt{!=} operators are numeric, they shall be subject to \{6.7\}: Type promotion». Otherwise, each operand must be of the same type, and that type must both be either \texttt{str}, \texttt{bool}, \texttt{rune}, or a pointer type.
6.6.42.7 The result of the \texttt{==} operator shall be \texttt{true} if the first operand is equal to second operand in value, and \texttt{false} otherwise.
6.6.42.8 The result of the \texttt{!=} operator shall be \texttt{true} if the first operand is not equal to second operand in value, and \texttt{false} otherwise.
6.6.42.9 Two `str` types shall be equal if both strings have the same length and octets. Otherwise, they shall not be equal.

6.6.42.10 The implementation shall ensure that any side-effects of the first term shall occur before side-effects of the second term.

### 6.6.43 Logical arithmetic

#### logical-and-expression

\[
\text{equality-expression} \\
\text{logical-and-expression} \ \&\& \ \text{equality-expression}
\]

#### logical-xor-expression

\[
\text{logical-and-expression} \\
\text{logical-xor-expression} \ ^\^ \ \text{logical-and-expression}
\]

#### logical-or-expression

\[
\text{logical-xor-expression} \\
\text{logical-or-expression} \ |\| \ \text{logical-xor-expression}
\]

6.6.43.1 For all cases of logical arithmetic, both terms shall be of the `bool` type, and the result type shall be `bool`.

6.6.43.2 `\&\&` shall compute a logical and operation, and shall be `true` if both terms are `true`, and `false` otherwise.

6.6.43.3 `^\^` shall be a logical exclusive or operation, and shall be `true` if the terms are not equal to each other, and `false` otherwise.

6.6.43.4 `|\|` shall be a logical or operation, and shall be `true` if either term is `true`, and `false` otherwise.

6.6.43.5 If the first term of `logical-and-expression` is `false`, or the first term of `logical-or-expression` is `true`, the implementation shall ensure that the side-effects of the second term do not occur.

### 6.6.44 If expressions

#### if-expression

\[
\text{if-expression:} \\
\text{if \ conditional-branch} \\
\text{if \ conditional-branch \ else \ if-expression} \\
\text{if \ conditional-branch \ else \ expression}
\]

\[
\text{conditional-branch:} \\
( \ \text{expression} \ ) \ \text{expression}
\]

6.6.44.1 An `if-expression` chooses which, if any, expression to evaluate based on a logical criteria. In `conditional-branch`, the result type of the first `expression` shall be `bool`. If a type hint is provided, the second `expression` shall receive it as a type hint.
6.6.44.2 When executing a conditional-branch, the implementation shall evaluate the first expression (the condition), and if true, the implementation shall execute the corresponding second expression (the branch), ensuring that all side-effects occur. If the condition is false, the branch shall not be executed and shall not cause side-effects.

6.6.44.3 In the second form, the first conditional-branch shall be executed. If it was false, the second-order if-expression shall be executed; otherwise not. In the latter case, any side-effects of the second condition or branch shall not occur.

6.6.44.4 In the third form, the conditional-branch shall be executed. If it was false, the expression shall be executed. The result value shall be selected from the result of the branch which is executed.

6.6.44.5 In the first form, the result type is void. In the second form, the result type is void unless the third form is present in the $N^{th}$-order sub-branch for any value of $N$. In this case, and in the case of the third form used in the first order, if a type hint is provided and all non-terminating branches are assignable to that type, the result type shall be the type given by the type hint. If all branches terminate, the result type shall be void and the if expression shall terminate. Otherwise, the result type shall be the 6.9 Result type reduction algorithm applied to the result types of the non-terminating branches.

6.6.45 For loops

```
for-loop:
  for ( for-predicate ) expression

for-predicate:
  expression
  binding-list ; expression
  expression ; expression
  binding-list ; expression ; expression
```

6.6.45.1 A for-loop executes its expression, the body of the loop, zero or more times, so long as a condition is true. Its result type is void.

6.6.45.2 In the first form, for-predicate specifies the condition with its expression. In the second form, the binding-list is the binding and the expression is the condition. In the third form, the first expression is the condition, and the second expression is the afterthought. In the fourth form, the binding-list is the binding, and the two expressions are respectively the condition and afterthought. The result type of the condition shall be bool, and this shall be provided as a type hint.

6.6.45.3 The implementation shall establish a new scope for the expression, then, if present, it shall evaluate the binding in this scope. The implementation shall then evaluate the condition. If it is true, the expression shall be evaluated and all of its side-effects shall occur; this process is an iteration. When the iteration is complete, the implementation shall evaluate the afterthought, if present, and then repeat the process, until the condition evaluates to false.
6.6.46 Switch expressions

switch-expression:
  \texttt{switch ( expression ) \{ switch-cases \}}

switch-cases:
  switch-case switch-cases_

switch-case:
  \texttt{case case-options \(\Rightarrow\) expression-list}
  \texttt{case \(\Rightarrow\) expression-list}

case-options:
  expression , opt
  expression , case-options

Forward references: \textit{\red{6.6.51: Compound expressions}}

6.6.46.1 A switch expression evaluates a value (\texttt{expression}, the \textit{switching expression}), then compares it with a number of switch-cases, taking whichever branch matches the value. The switching expression’s result type must either be numeric or be a \texttt{str}, \texttt{bool}, \texttt{rune}, or a pointer type.

6.6.46.2 Each of the case-options specifies a value to compare with, given by expression. This expression shall be limited to the \textit{\red{6.8: Translation compatible expression subset}}, and its result type shall be equivalent to the result type of the switching expression.

6.6.46.3 Each switch-case introduces an implicit \texttt{compound-expression} which the provided expression-list gives the expressions of. The implementation shall evaluate the expression-list of the corresponding switch-case if any of the case-options is equal to the switching expression’s result, setting the result of the overall switch expression to the result of the selected switch-case.

As such, the appropriate way to set the result of a switch expression is with a yield-expression. The semantics of defer-expression, bindings, and so on, are also implicated.

6.6.46.4 The form of switch-case without case-options indicates any case which is not selected by the other cases. Only one case of this form shall appear in the switch expression.

6.6.46.5 The switch cases shall be \textit{exhaustive}, meaning that every possible value of the switching expression is accounted for by a switch-case. It shall also be precisely exhaustive: no two cases shall select for the same value.

6.6.46.6 The implementation shall ensure that side-effects of the switch value expression occur before those of the selected case, and that side-effects of non-selected cases do not occur.

6.6.46.7 If a type hint is provided, each branch shall receive it as a type hint.

6.6.46.8 If a type hint is provided and all non-terminating branches are assignable to that
type, the result type shall be the type given by the type hint. If all branches terminate, the result type shall be `void` and the switch expression shall terminate. Otherwise, the result type shall be the "Result type reduction algorithm" applied to the result types of the non-terminating branches.

6.6.47 Match expressions

```
match-expression:
  match ( expression ) { match-cases }

match-cases:
  match-case match-cases_opt

match-case:
  case let name : type => expression-list
  case let ( binding-names ) : type => expression-list
  case type => expression-list
  case => expression-list
```

Forward references: "Compound expressions". "Variable binding"

6.6.47.1 A match expression evaluates a value (expression, the matching expression), then selects and evaluates another expression based on its result type. The result type of the matching expression must be a tagged union or nullable pointer type, or an alias of either.

6.6.47.2 If the matching expression has a tagged union type, each match-case shall specify a type which is either a member of that tagged union, or another tagged union which supports a subset of the matching expression’s type, or a type alias which refers to a qualifying type.

6.6.47.3 If the matching expression has a nullable pointer type, one match case shall be `null`, and another shall be the equivalent non-nullable pointer type, or a type alias which refers to a qualifying type.

6.6.47.4 Each match-case introduces an implicit compound-expression which the provided expression-list gives the expressions of. The implementation shall evaluate the expression-list of the corresponding match-case if the value of the matching expression is of the type specified by this match case, or can be assigned from it, setting the result of the overall match expression to the result of the selected match-case.

As such, the appropriate way to set the result of a match expression is with a yield-expression. The semantics of defer-expression, bindings, and so on, are also implicated.

6.6.47.5 The form of match-case without a type indicates any case which is not selected by the other cases. Only one case of this form shall appear in the match expression.

6.6.47.6 The first form of match-case, if selected, shall cause the implementation to cast the match expression to the selected type and assign the resulting value to name. It shall insert this binding into the scope of the implicit compound-expression of the
6.6.47.7 The second form of `match-case` is the *tuple unpacking* form, and in this case, the `type` shall be of a tuple type with a number of values equal to the number of items given in `binding-names`. The implementation shall cast the match expression to the selected type and create separate bindings for each name in `binding-names`, of the type of the corresponding tuple value, and initialize them to that value from the tuple. It shall insert this binding into the scope of the implicit `compound-expression` of the selected case.

6.6.47.8 If any name in `binding-names` is `_` (an underscore), a binding shall not be created.

6.6.47.9 The match cases shall be *exhaustive*, meaning that every possible type of the matching expression is accounted for by a `match-case`. It shall also be precisely exhaustive: no two cases shall select for the same type.

6.6.47.10 The implementation shall ensure that side-effects of the match value expression occur before those of the selected case, and that side-effects of non-selected cases do not occur.

6.6.47.11 If a type hint is provided, each branch shall receive it as a type hint.

6.6.47.12 If a type hint is provided and all non-terminating branches are assignable to that type, the result type shall be the type given by the type hint. If all branches terminate, the result type shall be `void` and the match expression shall terminate. Otherwise, the result type shall be the «6.9: Result type reduction algorithm» applied to the result types of the non-terminating branches.

### 6.6.48 Assignment

`assignment`:  

\[ \begin{align*} & \text{object-selector} \ \text{assignment-op} \ \text{expression} \\
& \star \ \text{unary-expression} \ \text{assignment-op} \ \text{expression} \\
& \text{slicing-expression} = \text{expression} \\
& (\ binding-names \ ) = \text{expression} \end{align*} \]

`assignment-op`: one of:

\[ += -= *= /= %= <<= >>= &= | &= \&\&= | &= ^\&= \]

Forward references: «6.6.49: Variable binding»

6.6.48.1 An `assignment` expression shall cause the object given by the first term to be assigned a new value based on the value given by the second term. The type of the object shall be provided as a type hint to the secondary expression. The result type of an assignment shall be `void`.

6.6.48.2 If the `assignment-op` is `=`, the first term shall be assigned the value given by the second term. Otherwise, the assignment `e1 op= e1` shall be equivalent to the assignment `e1 = e1 op (e2)`, but the side-effects of `e1` shall only occur once.

6.6.48.3 In the first form, the `object-selector` selects the object to be modified. The type of this object shall not be a `const` type.

6.6.48.4 In the second form, the `unary-expression` shall have a result of a non-nullable,
non-const pointer type, and the object which is assigned shall be the secondary object to which the pointer object refers. The second term shall be assignable to the pointer’s secondary type.

6.6.48.5 In the third form, the expression shall be either of a slice type and have a length equal to the slice given by slicing-expression, or an expandable array. The first term shall not be of a const type, and the lengths of the two slices shall be equal. The contents of the slice or expandable array given by the second term shall be copied into the slice given by the first term.

6.6.48.6 In the fourth form, the expression shall be of a tuple type, and shall have length equal to the number of binding-names specified. The implementation shall assign each value of the expression to the object given by the respective left-hand term. All left-hand terms shall be of a non-const type.

6.6.48.7 If any name in binding-names is _ (an underscore), a binding shall not be created, but any side-effects of the second term shall still occur.

6.6.48.8 The second term shall be assignable to the object. Assignability rules are stricter than castability rules. All types are assignable to themselves. The set of other types which are assignable to a given type are given by the following table:

<table>
<thead>
<tr>
<th>Object type</th>
<th>May be assigned from</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mutable type</td>
<td>Constant types assignable to the object type</td>
</tr>
<tr>
<td>Signed integer types</td>
<td>Signed integer types of equal or lower precision</td>
</tr>
<tr>
<td>Unsigned integer types</td>
<td>Uns signed integer types of equal or lower precision</td>
</tr>
<tr>
<td>Floating point types</td>
<td>Any floating point type of equal or lower precision</td>
</tr>
<tr>
<td>Nullable pointer types</td>
<td>Non-nullable pointer type of the same secondary type</td>
</tr>
<tr>
<td>Slice types</td>
<td>Array type of the same secondary type and definite length</td>
</tr>
<tr>
<td>Slice types</td>
<td>[]void</td>
</tr>
<tr>
<td>Array types of undefined size</td>
<td>Array types of defined size</td>
</tr>
<tr>
<td>Tagged union types</td>
<td>See notes</td>
</tr>
<tr>
<td>Type aliases</td>
<td>Any type assignable to the secondary type</td>
</tr>
<tr>
<td>void</td>
<td>Any type</td>
</tr>
<tr>
<td>* void</td>
<td>Any non-nullable pointer type</td>
</tr>
<tr>
<td>nullable * void</td>
<td>Any pointer type</td>
</tr>
</tbody>
</table>

The implementation shall perform any necessary conversion from the source type to the destination type.

6.6.48.9 Pointers to array types are mutually assignable if their secondary types are mutually assignable.

6.6.48.10 A pointer to a type is assignable to a pointer to a secondary type if the primary type is a struct type which contains the secondary type at offset zero, or if the type at offset zero is a type which would be assignable under these rules.

6.6.48.11 Tagged union types may be assigned from any of their constituent types. Tagged unions may also be assigned from any type which is assignable to exactly one of its constituent types. Additionally, tagged unions may be assigned from any other tagged union type, provided that the set of constituent types of the destination type is a superset of the set of constituent types of the source type.
6.6.48.12 **const** types have the same assignability rules as the equivalent non-const type. Types with the error flag set have the same assignability rules as the equivalent type with the flag unset.

6.6.48.13 If at least one of the types is a flexible constant, the 6.10: Flexible constant promotion algorithm shall be applied to them, and they shall be considered mutually assignable if the promotion succeeds.

In the context of an assignment expression, 6.6.48.2: Assignment prevents the modification of objects with a const type. However, the assignability rules are referred to in many other contexts throughout the specification, and in these contexts, unless otherwise specified, non-const types are assignable to const types. For example, a binding which specifies a const type may use a non-const type for its expression.

6.6.48.14 The implementation shall ensure that any side-effects of the first term shall occur before side-effects of the second term.

### 6.6.49 Variable binding

\[
\text{binding-list:} \\
\quad \text{static}_{\text{opt}} \ \text{let} \ \text{bindings} \\
\quad \text{static}_{\text{opt}} \ \text{const} \ \text{bindings}
\]

\[
\text{bindings:} \\
\quad \text{binding}_{\text{opt}} \\
\quad \text{binding} \ , \ \text{bindings}
\]

\[
\text{binding:} \\
\quad \text{name} = \ \text{expression} \\
\quad \text{name} : \ \text{type} = \ \text{expression} \\
\quad ( \ \text{binding-names} \ ) = \ \text{expression} \\
\quad ( \ \text{binding-names} \ ) : \ \text{type} = \ \text{expression}
\]

\[
\text{binding-names:} \\
\quad \text{name} , \ \text{name} \\
\quad \text{name} , \ \text{binding-names}
\]

6.6.49.1 A binding-list shall cause one or more objects to become available in the present scope. Each object shall be identified by its name, and shall have its initial value set to the result of the expression. The result type of a binding list expression is void.

6.6.49.2 In the first form of binding, the type of the object shall be equivalent to the result type of the expression. In the second form, the type shall be as indicated, and the result type of the expression shall be assignable to this type. In this second form, the type specified is used as a type hint for the expression.

6.6.49.3 The third and fourth forms of binding are the tuple unpacking form, and in this case, the type and expression shall be of a tuple type with a number of values equal
to the number of times name is given. The implementation shall create separate bindings for each name, of the type of the corresponding tuple value, and initialize them to that value from the tuple.

6.6.49.4 If any name is _ (an underscore), a binding shall not be created, but any side-effects of the initializer shall still occur.

6.6.49.5 If the const form is used, the type of each binding shall be modified to include the const flag. If the let form is used, the type of each binding which uses the first form of binding shall be modified to omit the const flag.

6.6.49.6 If the static form is used, the variables shall be allocated statically, such that they are only initialized once and their previous value, accounting for any later mutations, is preserved each time the binding expression is encountered, including across repeated or recursive calls to the enclosing function. In this case, the initializer must use the «6.8 Translation compatible expression subsets».

6.6.49.7 If a binding gives a name which is already defined in the current scope, the new binding shall shadow the earlier binding, causing any later references to this name to resolve to the newer binding.

6.6.49.8 The type of the binding shall not use a type which has a zero or undefined size. If the type of a binding is a flexible constant type, it shall first be lowered to its default type.

6.6.50 Deferred expressions

defer-expression:
   defer expression

6.6.50.1 A defer-expression causes another expression to be deferred until the termination of the current scope. The result type is void.

6.6.50.2 The implementation shall cause the expression to be evaluated upon the termination of the current scope, either due to normal program flow, or due to encountering a terminating expression.

6.6.50.3 If several expressions are deferred in a single scope, their side-effects shall occur in the reverse of the order that they appear in the program source.

6.6.50.4 If the current scope is terminated before a defer-expression (but not an expression which was already deferred) would be evaluated, the side-effects of the expression shall not occur.

6.6.50.5 A defer-expression shall not appear as a descendant of the expression tree formed by expression.
6.6.51 Compound expressions

expression-list:
  expression ; expression-list-opt
binding-list ; expression-list-opt
deref-expression ; expression-list-opt

compound-expression:
  label-opt { expression-list }

label:
  : name

6.6.51.1 A compound-expression evaluates any number of expressions in sequence. If a label is present, the expression is considered labelled.

6.6.51.2 The result of a compound-expression shall be void unless the expression is selected by one or more yield-expressions. In that case, the result type shall be the «6.9: Result type reduction algorithm» applied to the result types of the yield expressions.

6.6.51.3 If a type hint is provided to a compound-expression, the hint shall be provided to the expression of any yield-expression which selects that compound-expression.

6.6.51.4 The expressions shall be evaluated such that the side-effects of each all occur in the order that each expression appears.

6.6.51.5 If any of the expressions terminate, the compound-expression is considered to terminate, unless the expression which would cause the compound-expression is a yield-expression which selects this compound-expression’s scope. There shall be no expressions following the first terminating expression in a compound-expression.

6.6.51.6 The compound-expression shall establish a new scope whose parent is the scope in which the compound-expression resides.

6.6.52 Control expressions

control-expression:
  break label-opt
  continue label-opt
  return expression-opt
  yield-expression

yield-expression:
  yield
  yield expression
  yield label
  yield label , expression

6.6.52.1 A control-expression causes a selected expression to terminate in a specific way.

57
All control expressions are terminating expressions, and their result type is **void**.

6.6.52.2 The rules for selection of an applicable *expression* vary based on the kind of control expression used. If a label is used, it shall select the corresponding labelled *compound-expression* from the ancestors of the *control-expression*, and the selected expression shall meet the requirements for the appropriate control expression type. Otherwise, the first qualifying *compound-expression*, body of a *for-loop*, or body of a function-declaration is used, ordered such that the nearest ancestor is considered first. If no suitable *expression* is selected, a diagnostic message will be displayed and the translation phase shall terminate.

6.6.52.3 In the **break** and **continue** forms, the selected expression shall be the body of a *for-loop*. The **break** form shall cause the loop to end without evaluating the *condition* or the *afterthought*. The **continue** form shall cause the loop to repeat immediately, running the *afterthought* if present, re-testing the *condition*, and repeating the loop if **true**.

6.6.52.4 The **return** form shall select the body of a function-declaration. The expression shall be used as the result value for the function, or, if absent, **void** shall be used. This expression shall receive the function's result type as a type hint, and the result shall be assignable to that type.

6.6.52.5 The **yield-expression** form shall select any *compound-expression*. If an expression is provided, it shall not terminate, and shall be used as the result value for the *compound-expression*. See the description of *compound-expression* for details on the type semantics associated with a yield expression.

6.6.52.6 In any of these cases, if a *compound-expression* is selected, the implementation shall ensure that side-effects do not occur for any expressions which are lexically situated after the *control-expression*.

6.6.53 High-level expression class

```
expression:
    assignment
    logical-or-expression
    if-expression
    for-loop
    control-expression
```

6.7 Type promotion

6.7.1 The operands of some arithmetic expressions are subject to *type promotion*, to allow for arithmetic between disjoint types. The operand of lower precision may be promoted, or implicitly cast, to the precision of the more precise operand. Unless explicitly covered by the following cases, operands shall not be promoted, and the translation environment shall print a diagnostic message and abort for incompatible combinations of operand types.

6.7.2 For expressions where the result type is determined by type promotion, the result type shall
be equivalent to the type of the operand which has the highest precision.

6.7.3 For expressions involving at least one flexible constant type, the result type shall be determined by the »6.10 Flexible constant promotion algorithm».

6.7.4 For expressions involving two integer types, the type of lower precision may be promoted to the type of higher precision only if the signedness is the same for each operand.

6.7.5 Expressions involving $\text{uintptr}$ and $\text{size}$ promote to $\text{uintptr}$, expressions involving $\text{uintptr}$ and $\text{null}$ promote to $\text{uintptr}$, and expressions involving $\text{uintptr}$ and a pointer type promote to that pointer type. All other expressions involving $\text{uintptr}$ shall cause the translation environment to print a diagnostic message and abort.

6.7.6 An integer type may be promoted to an enum type whose storage is the same as the integer’s storage.

6.7.7 For expressions involving floating point types, $\text{f32}$ may be promoted to $\text{f64}$.

6.7.8 For expressions involving pointer types, $\text{null}$ may be promoted to any nullable pointer type, and a non-nullable pointer type may be promoted to a nullable pointer type with the same secondary type. Any pointer type may be promoted to a void pointer.

6.7.9 A mutable type may be promoted to a constant type which is otherwise equivalent to the mutable type, or any other type which that constant type may promote to.

6.7.10 A pointer type may be promoted to another pointer type if the secondary type of the pointer may be promoted to the secondary type of the second pointer.

6.7.11 An array type may promote to an array type with undefined size with an equivalent member type.

6.7.12 A non-aliased type A may promote to a type alias B if type A may promote to the underlying type of type B.

6.8 Translation compatible expression subset

The translation-compatible expression subset is a subset of expression types which the implementation must be able to evaluate during the translation phase.

6.8.1 The following expressions are included:
6.8.2 All terminals which are descendants of any of the listed terminals are included, and all 
non-terminals and terminals which are descendants of plain-expression are included.

6.8.3 The pointer dereference unary-expression (the * operator) shall be excluded from the 
translation-compatible expression subset. Additionally, the implicit pointer type derefer-
ence semantics of field-access-expression and indexing-expression are not available.

6.8.4 The expression used for a length-expression is not required to be translation-compatible as 
long as the result type is either an array type or an array type's alias, indirected via any 
number of non-nullable pointer types or their aliases if appropriate.

6.8.5 The implementation is not required to use a conformant implementation of the storage 
semantics of types in the translation environment, provided that there are not observable 
side-effects in the execution environment as a result of any differences.

6.8.6 In a context where an expression is constrained to this subset, the use of an expression type 
outside of this set shall cause the translation environment to print a diagnostic message and 
abort.

6.9 Result type reduction algorithm

6.9.1 The result type reduction algorithm shall operate on a list of types. It shall perform the 
following reductions in order:

1. Replace all tagged unions with their members

2. Remove all duplicate types

3. Remove all pointer types such that an equivalent nullable pointer type exists

4. Remove all mutable types such that an equivalent constant type exists

5. If null and exactly one pointer type remain, replace both with an equivalent nullable pointer 
type
6.9.2 If null and at least one other type remain after these reductions, the translation phase shall print a diagnostic message and abort.

6.9.3 If exactly one type remains, it shall be the result of the result type reduction algorithm. If more than one type remains, the result of the result type reduction algorithm shall be a tagged union containing the remaining types.

6.10 Flexible constant promotion algorithm

6.10.1 The flexible constant promotion algorithm shall operate on two types, at least one of which shall be a flexible constant type.

6.10.2 If both operands are ico\texttt{nst}, they shall both be lowered to ico\texttt{nst} with the minimum value set to the smaller of their minimum values and the maximum value set to the larger of their maximum values, and that type shall be the result.

6.10.3 Otherwise, if both operands are fconst or both are rconst, they shall both be lowered to a new fconst or rconst respectively, and that type shall be the result. If both operands are flexible constant types with different storages, the promotion shall fail.

6.10.4 If one operand is a tagged union type and promotion between exactly one of its members and the flexible constant type succeeds, the side-effects of that promotion shall occur and that member shall be the result of the promotion. Otherwise, if the constant’s default type is a member of the tagged union, the constant shall be lowered to its default type and the promotion shall succeed. Otherwise, the promotion shall fail.

6.10.5 If one operand is fconst and the other is a floating type, the fconst shall be lowered to the floating type, which shall be the result of the promotion. Otherwise, the promotion shall fail.

6.10.6 If one operand is ico\texttt{nst} and the other is a signed integer type, the promotion shall succeed if both the minimum and maximum values fields of the ico\texttt{nst} are within the limits of the other type. If one operand is ico\texttt{nst} and the other is an unsigned integer type, the promotion shall succeed if the maximum value of the ico\texttt{nst} is within the limits of the other type. If the promotion succeeds, the ico\texttt{nst} shall be lowered to the other type, which shall be the result of the promotion.

6.10.7 If one operand is rconst and the other is rune, the rconst shall be lowered into a rune. If one operand is rconst and the other is an integer type, the promotion shall succeed if the rconst value can be represented as the specified integer type without any data loss.
6.11 Declarations

declarations:
\[
\text{export}_{\text{opt}} \text{ declaration } ; \\
\text{export}_{\text{opt}} \text{ declaration } ; \text{ declarations}
\]

declaration:
\[
\begin{align*}
\text{global-declaration} \\
\text{constant-declaration} \\
\text{type-declaration} \\
\text{function-declaration}
\end{align*}
\]

A declaration specifies the interpretation and attributes of a set of identifiers.

6.11.1 The identifiers shall be visible anywhere within the current translation unit. If the export keyword is used, the identifiers shall be part of the unit’s exported interface.

6.11.2 The export keyword shall not be used with a function-declaration which uses the @init, @fini, or @test attributes.

6.11.3 Global declarations

global-declaration:
\[
\begin{align*}
\text{let} \quad \text{global-bindings} \\
\text{const} \quad \text{global-bindings}
\end{align*}
\]

global-bindings:
\[
\begin{align*}
\text{global-binding}_{\text{opt}} \\
\text{global-bindings} \quad , \quad \text{global-binding}
\end{align*}
\]
global-binding:
\[
\begin{align*}
\text{decl-attr}_{\text{opt}} \quad \text{@threadlocal}_{\text{opt}} \quad \text{identifier} : \quad \text{type} \\
\text{decl-attr}_{\text{opt}} \quad \text{@threadlocal}_{\text{opt}} \quad \text{identifier} : \quad \text{type} = \quad \text{expression} \\
\text{decl-attr}_{\text{opt}} \quad \text{@threadlocal}_{\text{opt}} \quad \text{identifier} = \quad \text{expression}
\end{align*}
\]

decl-attr:
\[
\begin{align*}
\text{@symbol} \quad ( \quad \text{string-constant} \quad )
\end{align*}
\]

6.11.3.1 In a global-declaration, sufficient space shall be reserved for each identifier in the global-bindings to store the type associated with it. That storage shall be initialized to the value of the expression and shall have alignment greater than or equal to the necessary alignment for the type. In the const form, the types shall have the constant flag enabled by default.

6.11.3.2 A global-binding’s expression shall be limited to the 6.8 Translation compatible expression subset, and shall be evaluated in the translation environment. If specified, the type of the value of the expression shall be assignable to type. If not specified, the type of the global-binding shall be the result of the expression.
6.11.3.3 The first form of global-binding is a prototype. In this form, the implementation shall not allocate storage for the global, and the programmer must arrange for storage to be provided elsewhere, e.g. during linking.

6.11.3.4 The interpretation of the @symbol form of decl-attr is implementation-defined.

The purpose of this directive is to allow users to customize the symbol name emitted for targets like ELF.

6.11.3.5 The interpretation of @threadlocal is implementation-defined.

The purpose of this directive is to store a separate copy of a global for each thread, similar to thread_local in C.

6.11.4 Constant declarations

constant-declaration:
  def constant-bindings

constant-bindings:
  constant-binding , opt
  constant-bindings , constant-binding

constant-binding:
  identifier : type = expression
  identifier = expression

6.11.4.1 In a constant-declaration, the identifiers in the constant-binding shall be available to the translation environment. No storage shall be allocated for them in the execution environment, and they shall not be addressable. References to them shall be equivalent to references to the expression associated with them, with a cast to type inserted.

6.11.4.2 A constant-binding’s expression shall be limited to the «6.8 Translation compatible expression subset», and shall be evaluated in the translation environment. If the first form of constant-binding is given, the type of the value of the expression shall be assignable to type.
6.11.5 Type declarations

type-declaration:
  type  type-bindings

type-bindings:
  type-binding  ,  opt
  type-binding  ,  type-bindings

type-binding:
  identifier  =  type
  identifier  =  enum-type

enum-type:
  enum  enum-storage  opt  {  enum-values  }

enum-values:
  enum-value  ,  opt
  enum-value  ,  enum-values

enum-value:
  name
  name  =  expression

enum-storage:
  integer-type
  rune

6.11.5.1 In a type-declaration, the identifiers shall declare type aliases. In the first form of type-binding, the underlying type for the identifier shall be the type. In the second form, the underlying type shall be enum-storage, if specified. Otherwise, the underlying type shall be int.

6.11.5.2 In the second form of type-binding, the enum values qualified with the binding’s identifier shall be made available to the translation environment. No storage shall be allocated for them in the execution environment, and they shall not be addressable.

6.11.5.3 If the enum-value does not specify a expression, the value assigned to that name is equal to the last value assigned to an enum-value of this enum type plus one. If no such previous value exists, zero is assigned.

6.11.5.4 An implicitly assigned enum-value shall not exceed the precision of the underlying integer type; if it were to, a diagnostic message shall be shown instead per «5.5: Diagnostics».

6.11.5.5 expression, if specified, shall be evaluated in the translation environment and the resulting value shall be assigned to the corresponding enum-value. The expression shall be provided the enum’s type’s underlying integer type as a type hint. The result type must be assignable to the enum type’s underlying integer type (ref «6.6.48: Assignment»).
6.11.5.6 A temporary scope shall be allocated while declaring an enum type, and each value name, in order, shall be made available to that scope.

*This allows the expression for each value to refer to previously declared values.*

6.11.5.7 Each enum-value’s name shall be unique within the set of all names of enum-values of the enum-type. Otherwise, a diagnostic message shall be printed and the translation phase shall be aborted.

6.11.5.8 expression shall be limited to the «6.8: Translation compatible expression subset».

### 6.11.6 Function declarations

*function-declaration:*

```
  fndec-attrs_opt fn identifier prototype
  fndec-attrs_opt fn name prototype = expression
```

*fndec-attrs:*

```
  fndec-attr
  fndec-attr fndec-attrs
```

*fndec-attr:*

```
  @fini
  @init
  @test
  fnctype-attr
dcl-attr
```

6.11.6.1 The first form of function-declaration is a *prototype*, and shall cause the identifier to refer to the function type described by the prototype and the function attributes. The implementation of this function shall be provided separately, or the translation phase shall fail.

6.11.6.2 The second form of function-declaration shall declare a function and its implementation. The result type of the expression shall be assignable to the prototype’s result type. The function shall be available in the unit scope by its name, and available to other units by forming a fully-qualified identifier from the unit namespace and the name.

6.11.6.3 In the second form of function-declaration, each parameter in the prototype which uses the name form shall be available within the expression by its name. Those which use the _ form shall not be made available.

6.11.6.4 The @fini form of fndec-attr shall cause the function to be a finalization function. @init shall cause it to be an initialization function. If multiple fndec-attrs of the same type are specified, the last one shall override all previous ones.

References: «??: Initialization functions», «??: Finalization functions»

6.11.6.5 Functions declared with @test, @init, or @fini shall accept no parameters, shall return void, shall not be declared with @noreturn, shall not appear in

65
object-selectors, need not have unique names, and shall not be inserted into the unit’s scope.

6.11.6.6 Other semantics of @test functions are implementation-defined.

6.12 Units

sub-unit:
    imports_{opt} declarations_{opt}

imports:
    use-statement
    use-statement imports

use-statement:
    use import-alias_{opt} identifier ;
    use import-alias_{opt} identifier :: { member-list } ;
    use identifier :: * ;

import-alias:
    name =

member-list:
    member , opt
    member , member-list

member:
    name = name

6.12.1 A unit, or translation unit, is composed of several source files as described by «5.3 Translation steps». Each source file is a sub-unit. A specific sub-unit may have no declarations, but the unit shall contain at least one declaration among its sub-units.

6.12.2 An import shall declare a dependency between this translation unit and another module of the namespace specified by the use-statement identifier. This shall cause the named module to be linked into the final program image as described by «5.3 Translation steps».

6.12.3 The first form of the use-statement shall cause the identifiers exported by the target module to become visible to this sub-unit in their fully-qualified form. Additionally, if the imported module has more than one namespace, identifiers of the form "x::y" shall be made available, where x is the most-specific namespace, and y is each of the exported members of the target module.

6.12.4 The second form of the use-statement shall cause only the members listed in the member-list, qualified in the context of the target namespace to become visible in their un-qualified form to this sub-unit.

6.12.5 A member in the first form shall become visible with the name given by its definition in the
target namespace. A member in the second form shall become visible with the name given by the first name in this form.

*In the use statement use bar::baz::{bat}, identifier bar::baz::bat may be referred to by its unqualified name bat in the scope of this sub-unit.*

6.12.6 The third form of the use-statement shall cause all identifiers qualified in the context of the target namespace to become visible in their un-qualified form to this sub-unit.

6.12.7 The forms with import-alias shall be equivalent to the forms without it except that the identifiers shall become visible under the namespace described by the name given in this form.

*In the use statement use foo = bar::baz;, identifiers in the namespace bar::baz will be visible under the namespace foo. For example, if the fully-qualified identifier bar::baz::bat exists, this sub-unit may refer to it as foo::bat.*

6.12.8 The translation unit shall establish a scope into which all unit-local declarations are inserted. Each sub-unit shall establish another scope as the parent scope of the unit scope, and in this sub-unit scope, each of the imports used by that sub-unit shall be made available.

*In other words, declarations made in a sub-unit are visible to other members of that unit, but imports in a sub-unit are not visible to other sub-units.*
